The Research and Technology Organization (RTO) of NATO

RTO is the single focus in NATO for Defence Research and Technology activities. Its mission is to conduct and promote cooperative research and information exchange. The objective is to support the development and effective use of national defence research and technology and to meet the military needs of the Alliance, to maintain a technological lead, and to provide advice to NATO and national decision makers. The RTO performs its mission with the support of an extensive network of national experts. It also ensures effective coordination with other NATO bodies involved in R&T activities.

RTO reports both to the Military Committee of NATO and to the Conference of National Armament Directors. It comprises a Research and Technology Board (RTB) as the highest level of national representation and the Research and Technology Agency (RTA), a dedicated staff with its headquarters in Neuilly, near Paris, France. In order to facilitate contacts with the military users and other NATO activities, a small part of the RTA staff is located in NATO Headquarters in Brussels. The Brussels staff also coordinates RTO's cooperation with nations in Middle and Eastern Europe, to which RTO attaches particular importance especially as working together in the field of research is one of the more promising areas of initial cooperation.

The total spectrum of R&T activities is covered by 7 Panels, dealing with:

- SAS Studies, Analysis and Simulation
- SCI Systems Concepts and Integration
- SET Sensors and Electronics Technology
- IST Information Systems Technology
- AVT Applied Vehicle Technology
- HFM Human Factors and Medicine
- MSG Modelling and Simulation

These Panels are made up of national representatives as well as generally recognised 'world class' scientists. The Panels also provide a communication link to military users and other NATO bodies. RTO's scientific and technological work is carried out by Technical Teams, created for specific activities and with a specific duration. Such Technical Teams can organise workshops, symposia, field trials, lecture series and training courses. An important function of these Technical Teams is to ensure the continuity of the expert networks.

RTO builds upon earlier cooperation in defence research and technology as set-up under the Advisory Group for Aerospace Research and Development (AGARD) and the Defence Research Group (DRG). AGARD and the DRG share common roots in that they were both established at the initiative of Dr Theodore von Kármán, a leading aerospace scientist, who early on recognised the importance of scientific support for the Allied Armed Forces. RTO is capitalising on these common roots in order to provide the Alliance and the NATO nations with a strong scientific and technological basis that will guarantee a solid base for the future.

The content of this publication has been reproduced directly from material supplied by RTO or the authors.

Preface

This volume provides abstracts and indexes for AGARD* unclassified publications during the period 1995-1998. By an arrangement with U.S. National aeronautics and Space administration (CASA) in Washington, DC, the computerized NASA STI Database has been used to prepare this publication.

Full bibliographic citations and abstracts for all the documents in this publication are given in the Abstract Section, which is organized in the major subject divisions and specific categories used by NASA in abstract journals and bibliographies. The subject divisions and categories are given in the Subject Categories list, together with a note for each that defines its scope and provides any cross-references. Within each category, the abstracts are arranged by document ID number.

Six indexes – Subject (based on NASA Thesaurus nomenclature), Personal Author, Panel, Report Number, ISBN and Document ID Number – are included.

Details of AGARD's classified publications for the same period are contained in a companion, classified, index.

This volume completes the series of paper indexes of AGARD publications for 1952-1998.

* AGARD and the Defense Research Group of NATO (DRG) merged on 1 January 1998 to form the Research and Technology Organization (RTO) of NATO. However, both AGARD and DRG continued to issue publications under their own names in 1998 in respect of work performed in 1997.

Préface

Ce volume contient des résumés et des indexes relatifs aux publications non-classifiées de l'AGARD parues entre 1995 et 1998. Selon l'accord qui existe entre l'AGARD et l'US National Aeronautics and Space Administration (NASA) à Washington DC, la base de données informatisée STI de la NASA a été utilisée pour la préparation de la présente publication.

Des résumés et des citations détaillés relatifs à tous les documents figurant dans cette publications sont inclus dans la section résumés de l'ouvrage, qui est organisée selon les domaines principaux et les catégories spécifiques employés par la NASA dans ses recueils de résumés et ses bibliographies. Les domaines et les catégories sont énumérés en anglais dans la liste en page v, avec une note pour chacun d'entre eux définissant son contenu et indiquant d'éventuels renvois. Les résumés sont classés par numéro d'identification à l'intérieur de chaque catégorie.

Six indexes en tout sont présentés, à savoir, Matière (selon la nomenclature du Thesaurus de la NASA), Auteur individuel, Panel, Numéro de rapport, ISBN et Numéro d'identification.

Le détail des publications classifiées de l'AGARD pour le même période est donné dans un autre index, classifié, dans la même série.

Ce volume complète les séries des papiers indexés des publications de l'AGARD pour la période de 1952 à 1998.

* L'AGARD a fusionné avec le Groupe sur la recherche pour la défense (GRD) le premier janvier 1998, pour former l'Organisation pour la recherche et la technologie de l'OTAN (RTO). Cependant, l'AGARD et le GRD ont continué d'éditer en 1998, sous leur propre noms, des publications relatives à leurs activités de 1997.

Subject Categories

AERONAUTICS For related information see also *Astronautics*.

- 01 **AERONAUTICS (GENERAL)** 1
- 02 **AERODYNAMICS** 7
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbo-machinery. For related information, see also *34 Fluid Mechanics and Heat Transfer*.
- 03 **AIR TRANSPORTATION AND SAFETY** 26
Includes passenger and cargo air transport operations; and aircraft accidents. For related information, see also *16 Space Transportation* and *85 Urban Technology and Transportation*.
- 04 **AIRCRAFT COMMUNICATIONS AND NAVIGATION** 37
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information, see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications Radar*.
- 05 **AIRCRAFT DESIGN, TESTING AND PERFORMANCE** 53
Includes aircraft simulation technology. For related information, see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics*. For land transportation vehicles, see *85 Urban Technology and Transportation*.
- 06 **AIRCRAFT INSTRUMENTATION** 96
Includes cockpit and cabin display devices; and flight instruments. For related information, see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography*.
- 07 **AIRCRAFT PROPULSION AND POWER** 103
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information, see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels*, and *44 Energy Production and Conversion*.
- 08 **AIRCRAFT STABILITY AND CONTROL** 120
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information, see also *05 Aircraft Design, Testing and Performance*.
- 09 **RESEARCH AND SUPPORT FACILITIES (AIR)** 129
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information, see also *14 Ground Support Systems and Facilities (Space)*.

ASTRONAUTICS For related information see also *Aeronautics*.

- 12 **ASTRONAUTICS (GENERAL)** 145
For extraterrestrial exploration, see *91 Lunar and Planetary Exploration*.
- 13 **ASTRODYNAMICS** N.A.
Includes powered and free-flight trajectories; and orbital and launching dynamics.
- 14 **GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE)** 146
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information, see also *09 Research and Support Facilities (Air)*.
- 15 **LAUNCH VEHICLES AND SPACE VEHICLES** 146
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information, see also *20 Spacecraft Propulsion and Power*.
- 16 **SPACE TRANSPORTATION** 147
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information, see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance*. For space suits, see *54 Man/System Technology and Life Support*.
- 17 **SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING** 148
Includes telemetry; space communication networks; astronavigation and guidance; and radio blackout. For related information, see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar*.
- 18 **SPACECRAFT DESIGN, TESTING AND PERFORMANCE** 148
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems, see *54 Man/System Technology and Life Support*. For related information, see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics, and 16 Space Transportation*.

N.A. — No abstracts were assigned to this category for this issue.

- 19 SPACECRAFT INSTRUMENTATION** 153
For related information, see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography*.

- 20 SPACECRAFT PROPULSION AND POWER** 153
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information, see also *07 Aircraft Propulsion and Power*, *28 Propellants and Fuels*, *44 Energy Production and Conversion*, and *15 Launch Vehicles and Space Vehicles*.

CHEMISTRY AND MATERIALS

- 23 CHEMISTRY AND MATERIALS (GENERAL)** 154

- 24 COMPOSITE MATERIALS** 155
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials*.

- 25 INORGANIC AND PHYSICAL CHEMISTRY** 160
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics*.

- 26 METALLIC MATERIALS** 162
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

- 27 NONMETALLIC MATERIALS** 166
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials*.

- 28 PROPELLANTS AND FUELS** 172
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power*, *20 Spacecraft Propulsion and Power*, and *44 Energy Production and Conversion*.

- 29 MATERIALS PROCESSING** N.A.
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology*.

ENGINEERING

- 31 ENGINEERING (GENERAL)** 186
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

- 32 COMMUNICATIONS AND RADAR** 193
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking*. For search and rescue see *03 Air Transportation and Safety*, and *16 Space Transportation*.

- 33 ELECTRONICS AND ELECTRICAL ENGINEERING** 237
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics*.

- 34 FLUID MECHANICS AND HEAT TRANSFER** 239
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics*.

- 35 INSTRUMENTATION AND PHOTOGRAPHY** 263
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing*. For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation*.

- 36 LASERS AND MASERS** 267
Includes parametric amplifiers. For related information see also *76 Solid-State Physics*.

- 37 MECHANICAL ENGINEERING** 269
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

- 38 QUALITY ASSURANCE AND RELIABILITY** 273
Includes product sampling procedures and techniques; and quality control.

- 39 STRUCTURAL MECHANICS** 275
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance*.

N.A. — No abstracts were assigned to this category for this issue.

GEOSCIENCES

- | | |
|--|-------------|
| 42 GEOSCIENCES (GENERAL) | N.A. |
| 43 EARTH RESOURCES AND REMOTE SENSING | 280 |
| Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see <i>35 Instrumentation and Photography</i> . | |
| 44 ENERGY PRODUCTION AND CONVERSION | N.A. |
| Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also <i>07 Aircraft Propulsion and Power</i> , <i>20 Spacecraft Propulsion and Power</i> , and <i>28 Propellants and Fuels</i> . | |
| 45 ENVIRONMENT POLLUTION | 288 |
| Includes atmospheric, noise, thermal, and water pollution. | |
| 46 GEOPHYSICS | 291 |
| Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see <i>93 Space Radiation</i> . | |
| 47 METEOROLOGY AND CLIMATOLOGY | 293 |
| Includes weather forecasting and modification. | |
| 48 OCEANOGRAPHY | 294 |
| Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also <i>43 Earth Resources and Remote Sensing</i> . | |

LIFE SCIENCES

- | | |
|---|-------------|
| 51 LIFE SCIENCES (GENERAL) | N.A. |
| 52 AEROSPACE MEDICINE | 295 |
| Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals. | |
| 53 BEHAVIORAL SCIENCES | 316 |
| Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research. | |
| 54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT | 332 |
| Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also <i>16 Space Transportation</i> . | |
| 55 SPACE BIOLOGY | N.A. |
| Includes exobiology; planetary biology; and extraterrestrial life. | |

MATHEMATICAL AND COMPUTER SCIENCES

- | | |
|---|-------------|
| 59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) | N.A. |
| 60 COMPUTER OPERATIONS AND HARDWARE | 343 |
| Includes hardware for computer graphics, firmware, and data processing. For components see <i>33 Electronics and Electrical Engineering</i> . | |
| 61 COMPUTER PROGRAMMING AND SOFTWARE | 344 |
| Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM. | |
| 62 COMPUTER SYSTEMS | 350 |
| Includes computer networks and special application computer systems. | |
| 63 CYBERNETICS | 352 |
| Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also <i>54 Man/System Technology and Life Support</i> . | |
| 64 NUMERICAL ANALYSIS | 355 |
| Includes iteration, difference equations, and numerical approximation. | |
| 65 STATISTICS AND PROBABILITY | N.A. |
| Includes data sampling and smoothing; Monte Carlo method; and stochastic processes. | |
| 66 SYSTEMS ANALYSIS | 356 |
| Includes mathematical modeling; network analysis; and operations research. | |
| 67 THEORETICAL MATHEMATICS | 370 |
| Includes topology and number theory. | |

N.A. — No abstracts were assigned to this category for this issue.

PHYSICS

- 70 **PHYSICS (GENERAL)** N.A.
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics*, *90 Astrophysics*, or *92 Solar Physics*.
- 71 **ACOUSTICS** 370
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution*.
- 72 **ATOMIC AND MOLECULAR PHYSICS** N.A.
Includes atomic structure, electron properties, and molecular spectra.
- 73 **NUCLEAR AND HIGH-ENERGY PHYSICS** N.A.
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation*.
- 74 **OPTICS** 372
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers*.
- 75 **PLASMA PHYSICS** N.A.
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics*. For space plasmas see *90 Astrophysics*.
- 76 **SOLID-STATE PHYSICS** N.A.
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers*.
- 77 **THERMODYNAMICS AND STATISTICAL PHYSICS** 376
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer*.

SOCIAL SCIENCES

- 80 **SOCIAL SCIENCES (GENERAL)** N.A.
Includes educational matters.
- 81 **ADMINISTRATION AND MANAGEMENT** 377
Includes management planning and research.
- 82 **DOCUMENTATION AND INFORMATION SCIENCE** 382
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software*.
- 83 **ECONOMICS AND COST ANALYSIS** N.A.
Includes cost effectiveness studies.
- 84 **LAW, POLITICAL SCIENCE AND SPACE POLICY** 387
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.
- 85 **URBAN TECHNOLOGY AND TRANSPORTATION** 387
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety*, *16 Space Transportation*, and *44 Energy Production and Conversion*.

SPACE SCIENCES

- 88 **SPACE SCIENCES (GENERAL)** N.A.
- 89 **ASTRONOMY** N.A.
Includes radio, gamma-ray, and infrared astronomy; and astrometry.
- 90 **ASTROPHYSICS** N.A.
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics*.
- 91 **LUNAR AND PLANETARY EXPLORATION** 387
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance*.
- 92 **SOLAR PHYSICS** N.A.
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation*.

N.A. — No abstracts were assigned to this category for this issue.

93 SPACE RADIATION

N.A.

Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine*. For theory see *73 Nuclear and High-Energy Physics*.

GENERAL

99 GENERAL

387

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

N.A. — No abstracts were assigned to this category for this issue.

ABSTRACT SECTION

01

AERONAUTICS (GENERAL)

19950017086 AVRO International Aerospace, Engineering Test Facilities., Woodford, United Kingdom
HEALTH AND USAGE MONITORING SYSTEMS: CORROSION SURVEILLANCE

Smart, J. D., AVRO International Aerospace, UK; Weetman, D. C., Real Time Corrosion Management Ltd., UK; AGARD, Corrosion Detection and Management of Advanced Airframe Materials; Jan 1, 1995, 11 p; In English; See also 19950017076; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

A predictive method of determining the inspection requirements for specific areas of individual aircraft could offer major advantages in terms of safety and maintenance and repair costs. An approach such as Health and Usage Monitoring in Service, in which the condition of components is monitored whilst in operation, would allow inspection requirements to be minimized and maintenance to be carried out as it becomes necessary. To use such an approach on aircraft would require very sensitive monitoring techniques. Modern electrochemical corrosion instrumentation could offer the required levels of sensitivity for detecting and characterizing the corrosion processes which precede the development of observable damage. This paper details a program carried out to assess the suitability of such electrochemical monitoring instrumentation for aerospace applications and to assess the feasibility of producing an aircraft system on which a predictive corrosion monitoring system could be based.

Because of projected reductions in future defense budgets, less money will be available for new aircraft acquisitions. Consequently, many of the current aircraft will have to be maintained well into the twenty-first century. As they continue to age, the time-dependent effects of material degradation, due to corrosion, will become more significant. Having to maintain aircraft three to four times their original design life presents a unique new set of complex technical problems and challenges. The primary concern is the reduction of airframe fatigue life and static strength due to widespread corrosion damage, fatigue, embrittlement, material loss due to corrosion, intergranular corrosion attack, fretting and stress concentrations. In an effort to ensure continued airworthiness and flight safety, an aggressive program plan has been developed and implemented at Tinker AFB to try to solve the corrosion problems and fatigue related problems to present the occurrence of catastrophic structural failures. The program consists of (1) invasive disassembly of a complete C/KC-135 and sections of B-52 and Boeing 707 aircraft, (2) corrosion documentation/information system development, (3) analysis and testing the effects of corrosion on structural integrity, as well as corrosion growth rates, (4) corrosion modeling and development of C/KC-135 service life extension strategies, (5) and comprehensive evaluation of non-destructive inspection/testing (NDI/NDT) equipment for hidden corrosion detection and quantification. This program has been extensively coordinated with USAF Wright Labs, AFOSR, Naval Air Warfare Center, FAA Aging Aircraft Center, NASA Langley, industry and academia.

The papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium on 'Aerodynamics and Aeroacoustics of Rotorcraft', which was held 10-13 October 1994 in Berlin, Germany are contained in this Report. In addition, a Technical Evaluator's Report aimed at assessing the success of the Symposium in meeting its objectives, and an edited transcript of the General Discussion held at the end of the Symposium are also included. The Symposium brought together scientists in different fields of aerodynamics and aeroacoustics to review and discuss their recent results in the area of rotary-wing aircraft in order to foster future development. The program included 35 papers from North American, Western Europe, and Russian organized in the following technical sessions: Dynamics Stall, Wind Turbines, Aerodynamic 3D Prediction Methods, Experimental Investigations of Helicopter Rotors, Acoustic Predictions Methods, and Interference Problems.

NEW DIRECTIONS IN ROTORCRAFT COMPUTATIONAL AERODYNAMICS RESEARCH IN THE US

Landgrebe, Anton J., United Technologies Research Center, USA; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 12 p; In English; See also 19960003572; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche; Original contains color illustrations

Recent research activities in the USA are presented that are representative of the directions of research for computational aerodynamics for rotorcraft. Emphasis is given to Navier-Stokes methodology for airflow and airload prediction, and specifically the fundamental technical challenges associated with grid systems and achieving wake generation without numerical diffusion. Although the current rotorcraft CFD methods have not yet generally demonstrated sufficient accuracy for the helicopter industry, the recent rate of progress is encouraging.

ROTORCRAFT SYSTEM IDENTIFICATION: AN OVERVIEW OF AGARD FVP WORKING GROUP 18

Hamel, Peter G., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Kaletka, Juergen, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 16 p; In English; See also 19960003572; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The AGARD FVP Panel, which for the last 20 years has sponsored activities in the field of flight vehicle system identification, decided in 1987 to set up the FVP Working Group 18, tasked with exploring and reporting on the topic of rotorcraft System Identification. Using flight test data bases from three different helicopters, specialists from research organizations and industry applied their individual eval-

01 AERONAUTICS (GENERAL)

uation techniques for data quality checking and for the identification and verification of flight-mechanical models. The accomplishments of the Working Group are documented in the Final Report. This paper gives a broad overview on the basic identification methodology and the practical approaches. Representative results are given to illustrate the main identification steps: specific flight test maneuvers and required measurements, definition of appropriate model structures, application of identification methods, and verification of the results. The Working Group mainly concentrated on the determination of 6 DOF rigid body models. Based on the experience gained in the Group, higher order models have recently been identified. Therefore, the paper also addresses the advances and gives an example for the application of the obtained models.

In a joint research program of NASA Ames Research Center, ZF Luftfahrttechnik, the German Aerospace Research Establishment (DLR), and EUROCOPTER Deutschland, a wind tunnel test was performed to evaluate the effects of Individual Blade Control (IBC) on rotor noise. This test was conducted in the 40x80 ft wind tunnel at NASA Ames Research Center, utilizing a full scale MBB-BO 105 four-bladed rotor system. Three microphones were installed for determination of the radiated noise, two of them on a moveable traverse below the advancing blade side and one in a fixed location below the retreating side. Acoustic results are presented for flight conditions with Blade-Vortex-Interaction (BVI) noise radiation. High noise level reductions were measured for single harmonic control inputs. In addition to the single harmonic inputs, multi-harmonic inputs were evaluated by superimposing 2/rev to 6/rev harmonics. For the first time the efficiency of sharp wavelets (60 deg and 90 deg width) on acoustic noise were measured. In order to achieve an adequate wavelet shape at the blade tip, corrections were made to account for the blade torsional behavior. In parallel with the acoustic measurements, vibratory loads were measured during the BVI flight condition to correlate the effects of IBC on noise and vibrations. It is shown how noise levels and vibrations are affected by specific IBC control inputs. In addition, correlations are made between noise levels and acoustic time histories with IBC phase and amplitude variations. For one IBC input mode with high noise reducing efficiency, a sweep of the moveable microphone traverse below the advancing side shows the effect on BVI noise directivity.

A STUDY OF BLADE-VORTEX INTERACTION AEROACOUSTICS UTILIZING AN INDEPENDENTLY GENERATED VORTEX

Kitaplioglu, C., NASA Ames Research Center, USA; Caradonna, F. X., Army Aviation Systems Command, USA; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 19 p; In English; See also 19960003572; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper presents results from an experimental study of rotor blade-vortex interaction (BVI) aerodynamics and acoustics. The experiment utilized an externally generated vortex interacting with a two-bladed rotor operating at zero thrust to minimize the influence of the rotor's own wake. The rotor blades were instrumented with a total

of 60 absolute pressure transducers at three spanwise and ten chordwise stations on both the upper and lower surfaces. Acoustic data were obtained with fixed near-field microphones as well as a movable array of far-field microphones. The test was carried out in the acoustically treated test section of the NASA Ames 80- by 120-foot Wind Tunnel. Several parameters which influence BVI, such as vortex-rotor separation distance, vortex strength, and vortex sense (swirl direction), as well as rotor tip Mach number and advance ratio, were varied. Simultaneous measurements were obtained of blade surface pressure distributions, near-field acoustics, and far-field acoustics during the vortex-blade encounters.

The paper presents a status of theoretical tools of AFDD, DLR, NASA and ONERA for prediction of the effect of HHC on helicopter main rotor BVI noise. Aeroacoustic predictions from the four research centers, concerning a wind tunnel simulation of a typical descent flight case without and with HHC are presented and compared. The results include blade deformation, geometry of interacting vortices, sectional loads and noise. Acoustic predictions are compared to experimental data. An analysis of the results provides a first insight of the mechanisms by which HHC may affect BVI noise.

THE ROLE AND STATUS OF EULER SOLVERS IN IMPULSIVE ROTOR NOISE COMPUTATIONS

Baeder, James D., Maryland Univ., USA; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 16 p; In English; See also 19960003572

Contract(s)/Grant(s): DAAL03-88-C-0002; DAAL03-92-G-0121; NAG2-898; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Several recent applications (in the last five years) of Euler solvers in the computation of impulsive noise from rotor blades emphasize their emerging role in complementing other methods and experimental work. In the area of high-speed impulsive noise the use of Euler solvers as research tools has become fairly mature with very favorable comparisons with experimental data, especially in hover. The grid sizes and resulting computational times are reasonable when compared to those required for accurate surface aerodynamics alone. Furthermore, Euler solvers have provided a rich database with the resolution and accuracy needed for input to Kirchhoff and acoustic analogy methods for predicting the far-field noise. On the other hand, the application of Euler solvers to calculate blade-vortex interaction noise is still far from mature. The computational resources required for accurate calculations away from the blade are much larger than for high-speed impulsive noise. Current calculations help improve the

basic understanding of the phenomena involved, but to date no comparisons with experiment have been made. Fortunately, the use of coupled Euler solver/Kirchhoff methods seems to offer promise for a robust and efficient technique for predicting both high-speed impulsive noise and blade-vortex interaction noise. Finally, a simple model problem of an isolated vortex interacting with an arbitrarily prescribed pitching airfoil demonstrates the feasibility of using Euler solvers to examine noise reduction techniques. The use of simple aerodynamic quasi-static theory and the computed lift time history as feedback to determine the required pitching motion appears sufficient to significantly dampen the unsteady loading and subsequent acoustics by an order of magnitude within a few blade passages.

A genetic algorithm coupled with a simplified acoustic analysis was used to generate low-noise rotor blade designs. The model includes thickness, steady loading and blade-vortex interaction noise estimates. The paper presents solutions for several variations in the fitness function, including thickness noise only, loading noise only, and combinations of the noise types. Preliminary results indicate that the analysis provides reasonable assessments of the noise produced, and that genetic algorithm successfully searches for 'good' designs. The results show that, for a given required thrust coefficient, proper blade design can noticeably reduce the noise produced at some expense to the power requirements.

Report No.(s): AGARD-AR-318; NIPS-95-06219; ISBN 92-836-1023-7; Avail: CASI; A21, Hardcopy; A04, Microfiche

This report presents the findings of a study performed by AGARD Working Group 17 into the current understanding of the aerodynamics of complex 3-D aircraft afterbodies and the status of the methods now available to aid in their design optimization. The major part of the report is given over to the results obtained and lessons learned from the application of current CFD procedures to a selection of test cases ranging in complexity from a simple axisymmetric body with jet to a twin jet body complete with wings and empennage. Comprehensive descriptions of the selected test cases with their experimental data bases are appended to the report in the hope that these will continue to serve other researchers in the field. Other sections of the report review the developments made in empirical/semi-empirical procedures and in the experimental techniques applicable to support both future computational developments and aid directly in the task of aircraft design optimization.

Lecture for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Aerothermodynamics and Propulsion Integration for Hypersonic Vehicles' have been assembled in this report. The following topics are covered: Aerothermodynamics of radiation-cooled surfaces; real-gas and strong interaction phenomena; hypersonic laminar-turbulent transition and turbulence modeling; configurational aerothermodynamics of reentry vehicles (winged and capsule) as well as RAM and SCRAM propelled vehicles; RAM and SCRAM inlet and propulsion integration; hypersonic missile aerothermodynamics and stage separation for two-stage launch configurations. In addition, the Hypersonic Aerothermodynamic Program at VKI was presented as well as a Navier Stokes-solver for hypersonic applications. The material assembled in this report was prepared under the combined sponsorship of the AGARD Fluid Dynamics Panel, the Consultant and Exchange Program of AGARD, and the von Karman Institute (VKI) for Fluid Dynamics.

Papers address examples of integrating advanced sensors, guidance control systems, and navigation systems. Methods for testing missiles, including lessons learned from Norway's testing of the Penguin Mk2, are discussed. Design issues, payloads and their associated technologies, and operational issues are examined in relation to Unmanned Air Vehicles (UAV). Specific systems described included: the French Self Contained Early Warning System against anti-ship missiles; the Phoenix; Boeing's helliwing; the Crecelle; and the US Navy's Tilt Rotor UAV demonstrator.

The RAF has been repairing helicopter composite rotor blades, fiber-glass radomes and panels on a variety of combat aircraft types for many years. However, the Service's main experience in the maintenance of carbon fibre composite (CFC) material has been related to the Harrier 2 aircraft. This paper describes the main CFC structures of

01 AERONAUTICS (GENERAL)

the Harrier 2 and outlines the variety of RAF peace-time, bolted structural repairs applied to the aircraft. Examples are provided of various simple and complex repairs.

Corrosion as an unavoidable fact requires cost effective control measures. By these control measures, aircraft life will be much longer in comparison with the precautions taken during the manufacturing of a/c. The main philosophy gained by the experiences of maintaining more than 5000 a/c is determined by detection and removal of corrosion, followed by renewal of the protective coating in the very early stages of corrosion. It has to be repeated in determined intervals, based on the lessons learned over the years. A steady development of new coating systems is associated with the elimination of toxic/hazardous chemicals and slower aging of the organics. With respect to human and environment protection, protective coatings, the problems of how to get the higher chemical and mechanical resistant coatings removed, and the goal of collecting all divergent properties under cost effective measures are the guidelines in the aircraft maintenance area.

This publication includes the papers presented in a NATO Advisory Group for Aerospace Research and Development (AGARD) Lecture Series. This Lecture Series considered the problems of integrating externally mounted weapons on helicopters. The focus is on aeromechanical and structural aspects, with additional discussion on operational issues. It addresses new aspects in the field of helicopter/weapon system integration; it places a strong emphasis on the lessons learned from recent experiences in actual development programs. The publication includes case histories of weapons integration on the AH-64 Apache, the RAH-66 Comanche, the EH-101, and the Tiger.

The helicopter is fast approaching a half century of service as a weapon system. From humble beginnings after World War 2, largely in the roles of observation platforms and search and rescue vehicles, rotorcraft have evolved to a principal in the modern battle scenario. In the war at sea, the helicopter forms an integral part of a task force capable of launching devastating firepower at surface and subsurface targets. In the airland battle, technology has made the helicopter into a tank killer, troop transport and night observation platform. Finally, in the most unlikely arena, air-to-air combat, modern weaponry has shown the helicopter to be effective against even high performance tactical aircraft.

Since the beginning of aircraft design and certification, loads and loads-related requirements have continued to evolve, while the initial conservative assumptions related to safety factors have remained essentially the same over the years. The technology and analysis tools have also evolved substantially in several areas: for example the increased use of computational/experimental methods in the areas of maneuvering loads; the characterization of buffet; the increased use of stochastic methods for gust loads; and the improved knowledge of fatigue life impact on design. On the other hand, the quest for lighter and higher performance aircraft led to the development of new technologies such as Electronic Flight Control Systems (EFCS) and thrust vectoring systems. With the increased use of these technologies and the improved quantification of factors influencing loads, the initial concept of safety factors and also some of the bases of military standards for military aircraft needed to be re-visited. It was observed in the Workshop that there was not much advantage in trying to reduce the safety factors for a new aircraft but that it might be effective to do so for an aircraft modification after a change of role, for instance. Reserves were also expressed as to the danger of optimizing a design for an initial use. It was considered advisable to remain conservative in order to accommodate changes in role during the life of an aircraft, especially a fighter aircraft. The effects of failures of EFCS on loads envelopes were also presented, showing that in certain cases an aircraft designed according to a functional EFCS could exceed the design load envelope when a failure of EFCS occurred, thus arguing for a certain conservatism in design. It was concluded, that some level of conservatism was still required but that new criteria and methods should be investigated in order to propose standards for future aircraft design.

FUTURE AEROSPACE TECHNOLOGY IN THE SERVICE OF THE ALLIANCE, VOLUME 2, MISSION SYSTEMS TECHNOLOGIES LES TECHNOLOGIES AERONAUTIQUES ET SPATIALES DU FUTUR AU SERVICE DE L'ALLIANCE ATLANTIQUE, VOLUME 2, LES TECHNOLOGIES DES SYSTEMES DE CONDUITE DE MISSION

Future Aerospace Technology in the Service of the Alliance; Dec. 1997; 184p; In English; In French; The AGARD Symposium on 'Future Aerospace Technology in the Service of the Alliance', 14-17 Apr. 1997, Palaiseau, France; See also 19980016572 through 19980016587

Report No.(s): AGARD-CP-600-Vol-2; ISBN 92-836-0048-7; Copyright Waived; Avail: CASI; A09, Hardcopy; A02, Microfiche

Advances in sensing and information processing/distribution technologies will enable highly innovative system concepts for achieving unprecedented improvements in military mission capabilities. Assessing those major technology advances, the symposium was structured in five sessions hosting twenty four papers: (1) Mission management concepts, introducing the subject, presenting technological requirements and giving as an example the unmanned tactical aircraft; (2) Sensors and electronic warfare, showing how emerging Radio Frequency and Electro-Optics technologies are able to offer improved situational awareness, but may also defeat apparently reliable weapons; (3) Information and communications systems, stressing the effective blending most likely to occur between market driven and specific military developments, as well as the need to account for the battlespace environment; (4) Information fusion and mission systems integration, demonstrating among others how data fusion which is required for matching the information rate to the human, will result in drastically improving its accuracy and reliability; and (5) System simulation, emphasizing the major role of simulation technologies for cost-effective design of new military systems, evaluation of existing ones, training of operators, and paving the way to the concept of synthetic environments. Based on emerging and rapidly evolving technologies, the presenters built a vision of future weapon systems capable of operating in a diverse range of hostile environments, under all weather conditions, and during day or night. Furthermore, autonomous situation appreciation capability, reliable communication channels and real-time decision aids were discussed, which will drastically reduce the operators' reaction time and prevent overload in a high target and threat density environment. The fruitful interaction with the audience confirmed the unique opportunity offered by this classified symposium to bring together experts working in the relevant sciences as well as the user community, and affiliated either with academia, industry, government organisations, or military services.

Volume 1, the summary volume, of the report of the NATO Advisory Group for Aerospace Research and Development (AGARD) study: 'Aerospace 2020'. This study explores the most advanced technologies, relevant to aerospace, being researched and developed in laboratories today. The study focuses on the most promising current technologies and the organizational and tactical consequences they will have at the field and system levels, over the course of the next 25 years. Topics include: a discussion of the impact of proliferation, human-machine interaction, synthetic environments, directed-energy weapons, information technologies, unmanned tactical aircraft, sub-orbital launchers, hypersonic missiles, and a discussion of affordability issues. Technologies are assessed from the viewpoints of both potential capabilities and threats. Observations and recommendations are presented.

Report No.(s): AGARD-CP-600-Vol-3; ISBN 92-836-0049-5; Copyright Waived; Avail: CASI; A19, Hardcopy; A04, Microfiche

Sustained Hypersonic Flight capability is envisioned for several future military and civilian applications, such as long range immediate reaction reconnaissance, high speed interception of air targets, long range precision strike against hardened or time critical targets, and access to space. The inherent reduction in time-to-target and low vulnerability will permit new operational tactics. The symposium outlined mission needs and operational scenarios for hypersonic vehicles. Addressed were: Technological issues and challenges in external hypersonic aerodynamics and design, propulsion and engine/airframe integration, military ramjet applications, overall system design including structures and materials development needs, and test facilities. Ground based test facilities cannot provide full simulation at Mach numbers above 5. Therefore, the use of Computational Fluid Dynamics design tools is essential. For routine use of the computational tools in analysis, design and optimization, it is necessary to reduce the time for the entire computational process by two orders of magnitude. Hypersonic boundary layer transition remains a critical design issue because of the important impact on engine drag and on heating, which can affect the choice of materials and thermal protection systems. In addition, reliable prediction of scramjet net thrust is an absolute must in resolving hypersonic air breathing vehicle design issues. Due to current facility and computational shortfalls, the development of future hypersonic flight systems requires research flight tests in the technology areas of boundary layer transition and air-breathing propulsion engine performance. For sustained hypersonic flight beyond Mach 6, the supersonic combustion ramjet (scramjet) engine is the only choice for the near future. Only this air-breathing concept offers a significant promise of large reductions in required propellant fractions, increased payload fractions, and reduced size vehicles, together with a foreseeable technological feasibility. Airframe/engine integration, combustor design and thermal management are the predominant engineering tasks. Fuels, hydrogen or hydrocarbon, must be matched to the operational needs of military or civil use. Experience in existing ramjet propelled missiles capable of speeds up to Mach 4 can support the development effort. The potential mission and cost benefits of sustained hypersonic flight to both military and civil applications are tremendous. From the budget point of view, the possibility of sharing development costs between military and civil programs offers a specific advantage.

REDUCING MAINTENANCE COSTS FOR COMBAT AIRCRAFT AIR FRAMES LA REDUCTION DES COUTS DE MAINTENANCE DES CELLULES D'AVIONS DE COMBAT

Chaumette, Daniel, Dassault Aviation, France; Armando, Patrick, Delegation Generale de l'Armement, France; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 12p; Summary translated by Schreiber; In French; See also 19980033517; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Maintaining a fleet of combat aircraft ready for operational employment for a group of missions with a fixed availability rate according to all evidence requires that all aircraft, during their service life, be subject to maintenance and inspection, or to repair or replacement; all of these activities are essential for flight safety. Different maintenance situations arise as a function of the critical nature and reliability of the systems involved, the scope of operations and their periodicity, as well as the required resources and skills. In this case, maintenance will be of the programmed type, i.e., of the planned type, and/or it will be unprogrammed and will focus on the air frame, the engine, the systems, and the equipment.

ADVANCES IN FLIGHT TESTING LES AVANCEES DANS LE DOMAINE DES ESSAIS EN VOL

Dec. 1997; 400p; In French; Flight Vehicle Integration Panel Symposium, 23-26 Sep. 1996, Lisbon, Portugal; See also 19980035005 through 19980035034

Report No.(s): AGARD-CP-593; ISBN 92-836-0050-9; Copyright Waived; Avail: CASI; A17, Hardcopy; A04, Microfiche

The Symposium comprised six sessions, each being devoted to a particular field, with one session on Systems Evaluation, including avionics, navigation, propulsion and weapons aspects, two sessions on Technological Advances covering all technical fields such as avionics software, simulation, instrumentation, aerodynamics, test methods etc., one session devoted to an Overview of Current Programmes, one session on Flight Dynamics, incorporating handling qualities, performance and flight controls, and one session addressing Management Problems in Testing. The symposium closed with a discussion between government representatives and manufacturers on "The role of governments in development testing in the 21st century".

C-17A AVIONICS FLIGHT TEST PROGRAM

MacLean, William J., Flight Test Squadron (418), USA; Dublenko, A. Lawrence, Aerospace Engineering Test Establishment, Canada; Advances in Flight Testing; Dec. 1997; 16p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

To date, the C-17A is one of the most advanced military airlift aircraft in the world. The corresponding avionics have reduced the number of crew members in the cockpit from four to two, and at the same time have increased the pilot's awareness of his aircraft's capabilities. The DT&E avionics program introduced many challenges to efficiently and adequately test the system to a high level of confidence before releasing the capability to the user. The use of effective test team structure helped to make the test program as efficient as possible, and the many lessons learned were incorporated into the program as testing progressed. As complex as the C-17A avionics

suite is, it is a highly capable system with room for growth to increase future capability. In December 1979, the USA Department of Defense launched the Cargo-Experimental (CX) program to define the capabilities needed in a new strategic airlift aircraft. The result was the C-17A Globemaster III which incorporates supercritical airfoil technology and winglets for long-range cruise performance as well as large externally blown flaps, full-span leading edge slats, spoilers, high sink-rate landing gear, anti-skid braking, and thrust reversers for rapid tactical descent and enhanced performance at short airfields. Further, the advanced C-17A integrated avionics suite, which consists of more than 60 remote terminals on nine different MIL-STD1553 busses, enables an aircrew of only two pilots and one loadmaster to carry out the C-17A long range heavy airlift mission. Test mission planning, test conduct, and analysis used both traditional and new test techniques to successfully accomplish the test mission. Lessons learned have been mostly in the realm of test planning and preparation. The sheer number of test points for the entire program (8000 total) and the manner in which testing was divided into aircraft systems contributed to inefficiencies in test flights. The C-17A avionics flight test program introduced many challenges to efficiently and adequately test a complex integrated avionics system to a high level of confidence before releasing capability to the user. The use of an effective test team structure and test planning helped to make the test program as efficient as possible, with many lessons learned being incorporated into the program as testing progressed. As complex as the C-17A avionics suite is, it is a highly capable system with room for growth to increase future capability.

Two components are required for analysis of dynamic aeroelastic phenomena, a structural finite element model of the vehicle, and an unsteady aerodynamics model; in current practice linear approximations are used for both models. Although structural nonlinearities possibly play a part in some cases of Limit Cycle Oscillation (LCO), the analysis community is generally content with existing structural modeling methods. The need for accurate and user-friendly advanced aerodynamic methods, however, is generally recognized. Control surface buzz, a one degree of freedom aeroelastic phenomenon involving shock oscillation, is an example of a problem not susceptible to analysis using linear aerodynamics. The current practice in industry is to use very conservative rules of thumb in hopes of preventing buzz, or simply to ignore the possibility. Obviously, conservatism introduces unnecessary weight and the discovery of a buzz problem during the test program causes delay and an expensive redesign effort. As computer hardware increases in capability, CFD methods are maturing and becoming available for at least limited use in industry. These methods hold much hope for future improvements in unsteady aerodynamics predictions. More accurate analysis of ordinary flutter in the sub- and supersonic flight regimes as well as the development of transonic analysis methods can result in a reduction of aircraft weight and development cost by reducing the need for conservatism and possibly by eliminating the expense of flutter model testing. Up to the present time, extreme difficulty of use, computational cost and lack of verification against suitable test cases have severely limited use of CFD procedures in industry; codes suitable for analysis of complete aircraft have not been shown to exist. The papers at this Workshop dealt with methods at the leading edge of current technology as applied in industry, and with more advanced methods which are in the development and checkout process. These papers contribute to the

expectation that the time is not far removed when industry will be able to make much increased use of advanced unsteady aerodynamics methods.

The papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium, "Advanced Aerodynamic Measurement Technology" are contained in this report. In addition, a Technical Evaluator's Report aimed at assessing the success of the Symposium in meeting its objectives, and an edited transcript of the General Discussion held at the end of the Symposium are also included. Measurement techniques were presented for flows from subsonic to hypersonic Mach numbers and environments from cryogenic to high-enthalpy reacting flows. Papers presented during the sessions addressed the following subjects: Particle Image Velocimetry; Doppler Global Velocimetry; Molecular Diagnostic Techniques; Holographic Interferometry; Skin Friction Measurements; Pressure Sensitive Paints; and Balance and Model Deformation Measurements.

A potential shortfall in U.S. tactical aircraft inventories required to meet future national and international defense contingency requirements early in the next century is projected to materialize some time during the period 2005-2015. The Uninhabited Combat Air Vehicle (UCAV) system concept has potential to help resolve the projected

inventory shortfall. Lockheed Martin Tactical Aircraft Systems (LMTAS) studies have identified a number of potential roles and missions in which the UCAV should be both cost and operationally effective. The UCAV concept, however, is unproven and needs system concept technology development, evaluation and demonstration if it is to be considered a viable candidate to meet the projected shortfall. A near-term development program that includes overall system simulation, evaluation and demonstration in combination with configuration specific and advanced technology development (ATD) will ensure that defense planners have a viable alternative ready for decision by the time the projected shortfall materializes.

Volume III is comprised of the technical papers supporting the report of the NATO Advisory Group for Aerospace Research and Development (AGARD) study: "Aerospace 2020". This study explored the most advanced technologies, relevant to aerospace, being researched and developed in laboratories today. The study focused on the most promising current technologies and the organizational and tactical consequences they will have at the field and system levels, over the course of the next 25 years. Topics include: a discussion of the impact of proliferation, human-machine interaction, synthetic environments, directed-energy weapons, information technologies, unmanned tactical aircraft, suborbital launchers, hypersonic missiles, and a discussion of affordability issues. Technologies are assessed from the viewpoints of both potential capabilities and threats. Observations and recommendations are presented. Volume II contains the conclusions of the report. Volume I is a short summary of these conclusions.

A review of experimental results from an ongoing study of the effects of compressibility on dynamic stall of an oscillating NACA 0012 airfoil is presented. The study shows that compressibility effects become significant at a free stream Mach number of 0.3. Dynamic stall is accelerated above this Mach number, but increasing unsteadiness delays onset of stall even under compressible flow conditions. Interferometric images of the flow show that process of dynamic stall occurs rapidly over a small angle of attack range. For certain flow conditions, multiple shocks form in the flow near the airfoil leading edge. The delay of stall has been shown to be due to delayed development combined with modification of the adverse pressure gradient in the flow. Transition has been shown to significantly modify the observed flow

behavior, and thus is a very important factor to be considered, especially since it occurs near the vortex formation location. Proper modeling of its effects is critical to dynamic stall flow computations.

EFFECT OF TURBULENCE MODELING ON DYNAMIC STALL COMPUTATIONS

Dindar, Mustafa, Turkish Aerospace Industries, Turkey; Kaynak, Unver, Turkish Aerospace Industries, Turkey; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 11 p; In English; See also 19960003572; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Dynamic stall phenomenon was studied numerically to investigate effects of turbulence modeling. An unsteady Navier-Stokes code capable of solving flow field around an airfoil undergoing unsteady harmonic motion was used for this purpose. A comparative study conducted between equilibrium and nonequilibrium turbulence models. It was found that, nonequilibrium effects play an important role in determining the separation and vortex shedding mechanisms of dynamic stall. First of all, in light stall, inadequacy of equilibrium models defeated by including nonequilibrium effects, and only Johnson-King model could be able to produce light stall hysteresis loop that is similar to experiment. Secondly, in the deep stall regime, vortex shedding mechanism was found to be greatly influenced by turbulence model.

INVESTIGATION INTO EFFECT PRODUCED BY BLADE AIRFOIL UNSTEADY AIRFLOW ON HELICOPTER MAIN ROTOR POWER REQUIRED

Ivtchin, V. A., Mil Moscow Helicopter Plant, Russia; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 8 p; In English; See also 19960003572; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

The paper presents the results obtained from the analysis of experimental data on the profile drag for pitch oscillating airfoils, as well as the technique developed for application of these data in calculations of helicopter main and tail rotors. The effect of the unsteady airflow on the profile drag was not taken into account. The reason is that it is very difficult to obtain experimental data. The existing analytical techniques of obtaining unsteady airfoil aerodynamic characteristics in a drained wing section allowed to determine only an average per cycle value of the profile drag. The problem of defining the profile drag of pitch oscillating airfoils has been more completely solved by V.E. Baskin. He has developed and successfully applied his unique method of defining aerodynamic characteristics of airfoils oscillating in the airflow. This approach has allowed to determine not only the pitch moment and lift values, but the instantaneous value of the profile drag as well. The data obtained from the experiments has been used to develop a method capable of calculating rotor shaft horsepower with due account of the profile drag characteristics. The analysis for forward flight conditions has been made by using the main rotor disc vortex theory. It has taken due account of the values of the pitch oscillating airfoil lift coefficient as well. The paper presents comparison of the instantaneous profile drag values versus the angle of attack data obtained from calculations and experiments.

DYNAMIC STALL CONTROL BY VARIABLE AIRFOIL CAMBER

Geissler, W., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Sobieczky, H., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 10 p; In English; See also 19960003572; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

In the present numerical investigations the unsteady flow about a helicopter airfoil section under deep dynamic stall conditions has been influenced by dynamic airfoil deformation. First attempts with a dynamic variation of the airfoil thickness have already shown the favorable effects on the dynamic stall phenomenon: the dynamic stall onset could be shifted to considerably higher incidences within the oscillatory loop. In the present paper the extension of this method to more arbitrary types of dynamic deformations is discussed and the influence of a dynamic change of the airfoil leading edge curvature (nose droop) is investigated in detail. Special emphasis is placed on the variation of the Mach number. It is shown that for incompressible flow ($M_{\infty} = 0.1$) the shedding of a dynamic stall vortex can be avoided at all. At a slightly higher Mach number ($M_{\infty} = 0.3$) however the complete suppression of the dynamic stall vortex is a much more difficult task. The present results show the way how to proceed successfully also in the compressible flow cases. Further it is obvious that the concept of deforming airfoils has considerable potential in other areas of helicopter aerodynamics, i.e. reduce or even avoid shock motion on the advancing side and therefore reduce the problem of compressibility noise radiation.

REVIEW OF RECENT AERODYNAMIC RESEARCH ON WIND TURBINES WITH RELEVANCE TO ROTORCRAFT. DATA (AND RIDDLES) ON DYNAMIC INFLOW, FLOW FIELD OF YAWED ROTORS, AND ROTATING 3-D STALL

Snel, H., Netherlands Energy Research Foundation, Netherlands; Vanholten, TH., Technische Univ., Netherlands; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 11 p; In English; See also 19960003572; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

A review is given of recent research on the aerodynamics of wind turbine rotors. The following subjects are covered in detail: (1) The induced velocity field of rotors, including dynamic inflow and yawed flow effects; and (2) Stall delay on rotation blades. A new boundary layer formulation is outlined applicable to this phenomenon. Without any further discussion, also some references have been given concerning recent wind turbine research on: (1) simulation methods of atmospheric turbulence; (2) dynamic stall effects, comparisons between theory and experiments; and (3) effect of several types of blade tips on radiated noise.

The dynamic stall on a NACA 0015 airfoil performing a rotation motion characteristic of Darrieus vertical-axis wind turbines is simulated using laminar and turbulent Navier-Stokes solvers. The numer-

ical results are compared with experimental data and show the importance of an adequate turbulence model to realistically simulate such a phenomenon. The differences between a Darrieus rotation motion and a pure pitching motion are also discussed.

STALL HYSTERESIS AND 3D EFFECTS ON STALL REGULATED WIND TURBINES: EXPERIMENT AND MODELLING

Madsen, H. A., Risoe National Lab., Denmark; Rasmussen, F., Risoe National Lab., Denmark; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 9 p; In English; See also 19960003572; Sponsored by the Danish Ministry of Energy; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

The stall regulation is used for control of maximum power and loads on a major part of wind turbines today of sizes up to 50-60 m in diameter. Operation with the blades partially or fully stalled is for this type of machines a part of their normal operating regime. Aeroelastic calculations below stall using 2D airfoil data give satisfactory results but in stall and above stall the calculations indicate self excited flap-wise vibrations. Fortunately, they are not in general confirmed by measurements. This discrepancy seems to be due to dynamic stall effects and the 3D airfoil characteristics for the rotating blade. Such airfoil characteristics have been measured on a 19 m stall regulated rotor and the deviations from 2D data are considerable. High normal force coefficients are measured at the root end and the lift curve has no negative slope up to 25-30 deg. angle of attack. Considerable stall hysteresis has been measured in normal operation and in particular during yawed operations. Measurements in a 4x4 m wind tunnel on the same blade has been carried out in order to determine the airfoil characteristics without the influence of rotation. This comparison indicates that rotational effects are of some importance for the discrepancy between 2D and 3D data. A CFD calculation on a simplified model of a rotating blade and at a low Reynolds number indicates that rotation does reduce the thickness of the separated boundary layer, resulting in the increased lift. Although the use of a stall hysteresis model in aeroelastic calculations generates damping and eliminates the self-excited vibrations, the problem still is to predict dynamic stall events, which have the correct power spectral characteristics.

INVESTIGATION OF THE YAWED OPERATION OF WIND TURBINES BY MEANS OF A VORTEX PARTICLE METHOD

Voutsinas, S. G., National Technical Univ., Greece; Belessis, M. A., National Technical Univ., Greece; Rados, K. G., National Technical Univ., Greece; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 11 p; In English; See also 19960003572; Contract(s)/Grant(s): JOU2-CT92-0186; JOU2-CT92-0113; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

A fully three-dimensional non-linear aeroelastic numerical investigation of the response of horizontal axis wind turbines during yawed operation was carried out. The numerical tool used, consists of a time-marching method based on the coupling of an unsteady free-wake vortex particle model and a 3D beam-type structural model. The investigation led to a complete data base of numerical results concerning the Tjaereborg wind turbine for which extensive full scale measurements of very good quality exist. Among the points that were given particular attention are: the effect of the root vortex, the coupling with

the shear of the inflow and the tower effect on the dynamics of the blades. Herein the most significant results are presented and discussed.

This paper presents the aerodynamic methods which are used currently at the Applied Aerodynamics Department of ONERA for the computation of helicopter rotors in hover and forward flight. They cover a wide range of algorithms, from classical blade element theory to more complex unsteady three-dimensional methods, each of them being well adapted to deal with a particular problem related to the helicopter main rotor. Typical applications for blade loads and dynamics, wake geometry, pressure distribution, performance prediction and parametric optimization are shown. Finally, the future trends in terms of CFD applications in the field of helicopter rotors at ONERA are given.

The 3D flowfield of a hovering rotor is calculated solving the Euler equations. Performing a grid refinement study it is demonstrated that an Euler method is able to capture the wake and vortices of a hovering rotor without any wake modelling. Accurate prediction of these rotational flow field phenomena needs fine grids with a high resolution in the complete region of the wake system. Additionally, high accuracy for the treatment of all numerical boundaries, which affect the vortex wake, is required. On the other hand, the investigations have shown that surface airloads are less effected by a more detailed resolution of the wake system. A second part of the study is concerned with wake capturing properties on block boundaries, especially on inner boundaries of overlapping grids. Overlapping grids are very attractive for the computation of a rotor in lifting forward flight or a rotor-body flowfield in hover. The effect of overlapping grids using the chimera technique is investigated comparing Euler solutions for a hovering rotor on a chimera grid system and on conventional single block and two block calculations. The chimera solution reproduces all flow features. The present implementation shows disadvantages concerning the detailed resolution of the wake system.

COST EFFICIENT CALCULATION OF COMPRESSIBLE POTENTIAL FLOW AROUND A HELICOPTER ROTOR INCLUDING FREE VORTEX SHEET BY A FIELD PANEL METHOD

Roettgermann, A., Stuttgart Univ., Germany; Wagner, S., Stuttgart Univ., Germany; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 10 p; In English; See also 19960003572 Contract(s)/Grant(s): DFG-WA424/8; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

To consider compressible transonic effects a vortex lattice method for the computation of the rotor flow is coupled with a field panel method. For this purpose Cartesian grids are used which are not adapted to the contour and only discretize the domain of the nonlinear flow. The basis for this procedure is the separation of the full potential equation into the Laplacian operator and the nonlinear terms. The developed program ROFPM is validated at several test cases of the CARADONNA rotor.

EVALUATION OF AERODYNAMIC AND DYNAMIC MODELS OF THE ROTORS OF HELICOPTERS BY CONFRONTATION TO THE EXPERIMENT EVALUATION DE MODELES AERODYNAMIQUES ET DYNAMIQUES DES ROTORS D'HELICOPTERES PAR CONFRONTATION A L'EXPERIENCE

Bessone, J., Office National d'Etudes et de Recherches Aeronautiques, France; Petot, D., Office National d'Etudes et de Recherches Aeronautiques, France; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 9 p; In French; See also 19960003572; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

This article presents the code of research 'ROTOR' developed with the ONERA and applied to the aeroelastic study of the rotors of helicopters. Confrontations of ROTOR with the experiment are then addressed. The core of the code calculates the equations of Lagrange associated with the rotor. Around various modules appear: methods of resolution, dynamic and aerodynamic models, formulations induced speeds. The structure of the rotor is regarded as a succession of basic transformations and the originality of ROTOR lies in the direct and automatic writing of the equations in matrix form. The confrontation of ROTOR with the experiment, first of all, showed the need for a very realistic modeling of the swirling wake. Locally, the dynamic model of stall ONERA clarifies very well the phenomenon of stall, improves calculations appreciably, but does not always allow to reach the experimental lift. The introduction into ROTOR of the semi-empirical correction of Houwink reduces the deficit of lift in the area of the strong stalls. Moreover, at the time of preliminary results, the models of Hopf reveal the oscillatory phenomena of the lift observed in experiments in this area. But the use of non-rectangular tips of blade will require, for the calculation of the effort aerodynamics buildings and of the deformations of blade, a finer analysis of the three-dimensional effects of end that only an aerodynamics of the CFD type seems to be able to estimate correctly.

FLOW FIELD INVESTIGATION OF A ROTATING HELICOPTER ROTOR BLADE BY THREE-COMPONENT LASER-DOPPLER-VELOCIMETRY

Seelhorst, U., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Beesten, B. M. J., Technische Univ., Germany; Buettelisch, K. A., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 12 p; In English; See also 19960003572; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The measurement of three dimensional local flow vectors of a blade tip vortex at positions near the helicopter rotor plane were

performed with a three component laser-Doppler-velocimeter (3D LDV). A 'position monitoring system' synchronized to the blade rotation gave access to blade motion parameters like lead-lag and pitching at the desired radial position of the blade. Mainly results concerning the structure of blade tip vortices were obtained. The measurements of a vortex generated at hover condition showed the correctness of 'time history' data acquisition, e.g. taking data during the time interval when one particular blade is passing the location of the measuring volume of the LDV. Vortex structure measurements at two different blade tips, a regular square tip for reference and a non-planar tip called winglet, were carried out. First of all the influence of the winglets on vortex structure and blade vortex interaction (BVI) has been investigated. Then in addition to the vortex parameters like vortex/blade miss distance, vortex core size, axial velocity deficit, vortex strength, and vorticity distribution with respect to the spatial orientation of the vortex axis, results on 3D-vorticity distribution and the temporal vortex roll up for the different blade tip vortices have been obtained.

A BOUNDARY INTEGRAL METHOD FOR UNIFIED TRANSONIC AERODYNAMIC AND AEROACOUSTIC ANALYSIS OF HOVERING ROTORS

Gennaretti, M., Rome Univ., Italy; Iemma, U., Rome Univ., Italy; Morino, L., Rome Univ., Italy; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 10 p; In English; See also 19960003572; Sponsored by Agusta Eli S.p.A.; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

The subject of this paper is the unified aerodynamic and aeroacoustic analysis of transonic hovering rotors. The aerodynamic/aeroacoustic problem is stated in terms of the velocity potential, whereas the solution is determined by applying a shock-capturing boundary integral formulation. Particular emphasis is given to the analysis of the non-linear terms in the equation for the velocity potential, whose contribution cannot be neglected for the transonic flow case analysis. Their contribution is expressed in a conservative form. Starting from the solution for the potential, the Bernoulli theorem is used to determine both the pressure distribution on the body surface (aerodynamic solution) and the acoustic pressure in the field (aeroacoustic solution). Numerical results are presented in order to show the capability of the methodology in determining both the aerodynamic and aeroacoustic solutions for transonic rotor configurations.

SEPARATION OF LIFTING VEHICLES AT HYPERSONIC SPEED WIND TUNNEL TESTS AND FLIGHT DYNAMICS SIMULATION

Sachs, G., Technical Univ. of Munich, Germany; Schoder, W., Technical Univ. of Munich, Germany; Kraus, W., Deutsche Aerospace A.G., Germany; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 8 p; In English; See also 19960003881; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Several topics of the separation maneuver of two-stage hypersonic vehicles are considered. Results which have been obtained from wind tunnel tests of the separation maneuver and related investigations on flight dynamics will be presented. In test facilities of DLR (Cologne), the aerodynamics characteristics of a two-stage space transportation system were investigated. The test campaign was focused on aerodynamic interference effects which exist when the two stages are in close proximity. The results of the wind tunnel tests provide a detailed data base for flight mechanics investigations. Numerical simulation of flight dynamics based on a well founded aerodynamics model is an appropriate technique to investigate such a highly dynamic maneuver. Control of both vehicles for achieving an optimal motion of the system is investigated. In addition, adequate stability and control characteristics from a piloting point of view are considered. Particular emphasis is put on a robust control technique. This is because robust control is an adequate means for dealing with

a system which shows great changes. During close proximity of the first and orbital stages, system changes are due to the separation maneuver itself because of aerodynamic interference effects.

WIND TUNNEL FLUTTER TESTING ON SHINGLES IN THE TRANSONIC AND SUPERSONIC SPEED REGIME**

Persoon, Albert J., National Aerospace Lab., Netherlands; Nov. 1995; 16p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Various types of shingles, being part of the heat protection system of re-entry vehicles, were investigated in the transonic and supersonic speed regime using NLR's High Speed (HST) and Supersonic (SST) wind tunnels. The investigations were carried out in close cooperation with Marcel Dassault Aviations (AMD) and Daimler Benz Raumfahrt Infrastruktur GmbH (DASA-RI). A review is given of the wind tunnel experiments with emphasis on the generation and control of noise levels of the boundary layer in which the shingles were placed during the tests. The use of a spoiler or suction of the flow, both affecting the flutter characteristics of a shingle, will be discussed. The behavior of unsteady pressures close to the shingle (upstream and downstream) is highlighted as these pressures might act as a monitoring device to define the onset of flutter or limit cycle oscillations of a panel.

A QUARTER CENTURY OF NASA WIND-TUNNEL AND FLIGHT EXPERIMENTS INVOLVING AEROSERVOELASTICITY

Noll, Thomas E., NASA Langley Research Center, USA; Perry, Boyd, III, NASA Langley Research Center, USA; Perry, Boyd, III, NASA Dryden Flight Research Center, USA; Nov. 1995; 12p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Over the past quarter century, the NASA Langley Research Center (LaRC) and the NASA Dryden Flight Research Center (DFRC) have played major roles in the development, demonstration, and validation of aeroservoelastic modeling, analysis, design, and testing methods. Many of their contributions resulted from their participation in wind-tunnel and flight-test programs aimed at demonstrating advanced active control concepts that interact with and/or exploit the aeroelastic characteristics of flexible structures. Other contributions are a result of their interest in identifying and solving adverse aeroservoelastic interactions that allow unique flight-test demonstrations or flight envelope clearance programs to be successfully completed. This paper provides an overview of some of the more interesting aeroservoelastic investigations conducted in the transonic dynamics tunnel (TDT) at LaRC and in flight at DFRC. Four flight-test projects are reviewed in this paper. These test projects were selected because of their contributions to the state-of-the-art in active controls technology (ACT) or because of the knowledge gained in further understanding the complex mechanisms that cause adverse aeroservoelastic interactions.

PRESSURE DRAG INDUCED BY A SUPERSONIC FLOW OVER CAVITIES

Zhang, Xin, Southampton Univ., UK; Feb. 1996; 10p; In English; See also 19960022326; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Pressure distribution and pressure drag due to a supersonic flow over a dual cavity geometry were studied at Mach 1.5 and 2.5. The study was performed numerically and results compared with an earlier

experiment. The mass-averaged Navier-Stokes equations were solved using a finite-volume scheme. The inviscid cell interface fluxes were estimated using Roe's approximate Riemann solver with a second-order extension. Turbulence was modeled using a two-equation k-z model with compressibility corrections. Two test configurations were selected: (1) a length to depth ratio $L/D = 1$ cavity followed by another $L/D = 1$ cavity separated by a distance of $1D$, and (2) an $L/D = 3$ cavity followed by an $L/D = 1$ cavity separated by a distance of $3D$. The pressure and drag of the individual cavity was compared with those of a single cavity of same L/D . It was found that the pressure field around the $L/D = 1$ was substantially modified by a preceding $L/D = 3$ cavity.

A computational capability has been developed for predicting the flow field in a three-dimensional weapons bay (or cavity). Computations have been performed for an empty bay and for a store placed within the weapons bay. The chimera overset grid methodology, a domain decomposition strategy, is used to simplify mesh generation. An implicit Navier-Stokes code with a thin-layer approximation is used to compute the weapons bay flow field at free-stream Mach numbers of 0.6, 0.95, and 1.20. The computational results are compared to experimental results for time-averaged pressure coefficients, overall sound pressure levels, and the frequency spectrum of the sound pressure levels on the bay walls. In addition, loads on a store placed within the bay are computed.

The results of the phase 1 effort conducted under AGARD Working Group 18 on Hypersonic Experimental and Computational Capability, Improvement and Validation are presented in this report. A discussion of issues and problems classified into seven topic areas precedes the individual sections on Shock/Boundary-Layer Interactions, Laminar-Turbulent Transition, Rarefield Flow, Real-Gas Effects, Facility Calibration Procedures, Extrapolation to Flight and Hypersonic Test Facilities. Recommendations for future work in these areas is included at the end of each section. Conclusions for the work conducted during the phase 2 of this Working Group will be presented in Volume 2.

Research at the University of Glasgow, based around implicit methods for solving the Euler and Reynolds' averaged Navier-Stokes equations, has targeted advanced computational fluid dynamics (CFD) methods for tackling complex flow fields of interest to aerospace vehicle designers. The requirements for this application are for efficient, high resolution schemes which can be ported to various massively parallel processors (MPP) systems and implemented with a robustness to give fast turn around times at competitive costs. It is recognized that the most demanding topics concern unsteady viscous flows and thus time accuracy and efficiency is pursued as a high priority. This paper reviews the work, ongoing and planned, by the team at Glasgow in code developments embracing future computing environments and including some results not previously published. The example test cases used in the performance and sensitivity studies include transonic flow results on the RAE 2822 airfoil and ONERA M6 wing selected by AGARD. The computing environment to which the codes port include workstations, either used singly or clustered to provide a parallel computing domain, and also integrate distributed memory supercomputers such as CRAY T3D and Intel Hypercube systems. The paper outlines these technologies also.

The Aeronautics/Aerospace Department of the von Karman Institute has been involved in research activities in the hypersonic regime since the 1960's with the installation of the hypersonic free piston tunnel Longshot, which allows to simulate high Reynolds number hypersonic flows. Since then, a Mach 6 blow down facility H3 is also operational and at present time an induction heating facility called Plasmatron is being developed under supervision of the European Space Agency. Simultaneously to the development of experimental techniques, Computational Fluid Dynamics was initiated and in-house made codes are operational to simulate hypersonic flows without chemistry and in thermal equilibrium. The objective of the present paper is to briefly describe the research topics which have been addressed the past years and the current activities at the VKI in the hypersonic aerothermodynamics area. Basic research topics will be first presented and then applications to hypersonic vehicles and development of facilities will be discussed.

A parallel perfect gas flow solver for axisymmetric applications is described. For the spatial discretization of the convective fluxes it uses a multidimensional upwind, monotonic shock capturing, matrix distribution scheme on a compact stencil (at most the points used by the Galerkin finite element discretization) in an unstructured grid, and the Galerkin finite element method for the viscous part. For fast convergence towards steady state a fully parallel implicit Newton algorithm has been implemented, where the resulting linear systems are solved by subdomain block ILV(0) preconditioned GMRES. A vertex-oriented domain decomposition is used allowing an efficient parallel preconditioner for the GMRES. As the linear systems themselves are solved on the complete grid, the convergence is practically independent of the way the grid is decomposed into subdomains. The message passing library MPI was used for the communication to make the code as portable as possible. Applications are shown for a hypersonic cone-fare configuration at different Mach and Reynolds numbers and a detailed comparison is made with a structured grid standard Finite Volume solver (the VKI-MB code). Results have been obtained on a four and eight processors SP2 demonstrating the robustness and efficiency of the new flow solver.

HYPERSONIC LAMINAR-TURBULENT TRANSITION AND ITS IMPLICATIONS FOR WINGED CONFIGURATIONS

Poll, D. I. A., Cranfield Univ., UK; Oct. 1996; 24p; In English; See also 19970009247; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The problem of laminar-turbulent transition on swept back wings travelling at hypersonic speeds has a great practical significance. Swept back wings support three-dimensional boundary layer flows and, in consequence, two mechanisms for transition are admitted which do not occur in two-dimensional situations. These are attachment-line contamination and cross-flow instability. Both these are known to be very important in the generation of turbulent flow in low-speed flows. It is argued that these phenomena are also important in high speed conditions. Available evidence is reviewed and, when possible, estimates are made of the conditions necessary for the transition onset.

Within the German Hypersonics Technology Program, a Technology Development and Verification study was performed in order to structure the European Technology Maturation and Verification Phase. Elements of this study are discussed in this contribution. After an introduction to the topic, a classification of hypersonic vehicles is given and the general design process is sketched. The structure of the German Technology and Verification Study is shown, and the reference concept and the major flight parameters are presented. An assessment of aerothermodynamics simulation means is given along with a consideration of some selected results of sensitivity studies and

an explanation of the Transfer Model approach, which was developed in the study. Some remarks on flight testing with experimental vehicles are followed by the summary of the results of the study.

The growth of commercial aviation has placed such demand on the air traffic system that many major U.S. airports are capacity limited and are experiencing significant traffic delays. These delays inconvenience passengers, cost the aviation industry hundreds of millions of dollars each year, and limit further growth of traffic. The existing wake turbulence separation distances represent a major challenge in ameliorating this congestion. To facilitate the introduction of the airplanes now categorized as 'heavy,' U.S. manufacturers worked with the Federal Aviation Administration (FAA) to conduct flight-test evaluations of the hazards of wake turbulence. These tests underscored, among other things, the necessity of three-dimensional flight path control. In light of the flight test findings, the FAA's effort focused on three areas: aircraft categories, air traffic control (ATC) procedures, and piloting procedures.

The interaction between two symmetrically located finite Rankine vortices and an elliptically loaded vortex sheet is examined in the Trefftz plane for a range of flow parameters. The Rankine vortices, which are placed over the sheet, have vorticity of opposite sign to that of the adjacent section of the sheet. They may be considered to represent, in the Trefftz plane, vortices 'injected' into the flow from an upstream location. It is shown that there are in general three types of interactions which significantly affect the rolling up process. Accordingly, an interaction can result in straightforward merging, formation of subsidiary structures or considerable inboard displacement of the rolling up tip vortex. In the last case, the process should help to enhance the onset of the Crow instability considerably.

FLOWFIELD PREDICTION OF THREE-DIMENSIONAL WING TRAILING VORTICES USING ADVANCED TURBULENCE MODELS

Eaton, J. A., University Coll., Ireland; OFlaherty, M. P., University Coll., Ireland; The Characterisation and Modification of Wakes from Lifting Vehicles in Fluids; Nov. 1996; 8p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The feasibility of employing a general-purpose Navier-Stokes code, in conjunction with a Reynolds stress transport turbulence model, for predicting wake vortex flow fields is investigated. Two test cases are considered, each employing two different turbulence models, a kappa-epsilon model, which is isotropic, and an anisotropic, differential Reynolds stress model. First the flow field around a low aspect ratio wing in a wind tunnel is computed to assess the influence of the surface and velocity distributions in the wake, particularly the stream-wise component, are compared with measurements. Although the grids used are suboptimal, predictions indicate a qualitative improvement for the anisotropic model, in particular where the swirl component of the flow is greater, such as in the vortex core. Next, wind tunnel data are used as a starting point for an axisymmetric model of a free vortex with axial flow. These computations allow the effects of choice of turbulence model on the aging and decay of a vortex in the far field to be observed. The kappa-epsilon model predicts a rapid growth of the vortex, whereas the differential Reynolds stress model results in a more realistic, almost uniform evolution of the core radius.

AN UNSTEADY VORTEX WAKE MODEL FOR MANEUVERING VEHICLES

Mendenhall, M. R., Nielsen Engineering and Research, Inc., USA; Perkins, S. C., Jr., Nielsen Engineering and Research, Inc., USA; Nov. 1996; 12p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A preliminary-design and analysis capability applicable to vehicles in unsteady maneuvers involving nonlinear, time-dependent flow conditions is described. The approach is a direct coupling of fluid dynamics and flight mechanics for use in the flight regimes where the flow phenomena are dominated by vorticity and separation associated with high angles of attack and rapid motions. The modularized computer algorithm is based on mathematical flow models, supplemented by empirical information where necessary, which accurately represent the physics of complex flows. This physics-based method is applicable to generic configurations, and it is not dependent on specific empirical information, and it is economical to use. The resulting method can be used as a prediction capability for specified

02 AERODYNAMICS

vehicle motions or flow conditions, or it can be coupled with a six-degree-of freedom equation-of-motion solver to predict flight trajectories and transient performance characteristics.

EXPERIMENTAL ASSESSMENT OF THE EXTENDED BETZ METHOD FOR WAKE VORTEX PREDICTION

Graham, W. R., Cambridge Univ., UK; Nov. 1996; 12p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The extended Betz method, whereby wake vortex velocity predictions are obtained from a given wing lift distribution, is assessed by comparison with experimental results for wake cross-flow velocities behind a wing model with flaps. The required lift distributions are found from overall lift data and a lifting-line calculation, and the comparison is made for both clean and high-lift fundamental Betz assumption of effectively two-dimensional, inviscid flow in the wake is well supported, but that a proposed approximate invariant, the second moment of vorticity, is not conserved. In spite of this, the theoretical predictions for the single vortex shed by each half of the clean wing are found to be accurate. However, the multiple vortices arising from the wing in high-lift configuration are not as well predicted, and in this case the usefulness of the method seems to be restricted to providing estimates of the number of vortices, and their overall circulations.

STRUCTURE, TRAJECTORY AND STRENGTH OF B747 AIRCRAFT WAKE VORTICES MEASURED BY LASER

Vaughan, J. M., Defence Research Agency, UK; Brown, D. W., Defence Research Agency, UK; Constant, G., Defence Research Agency, UK; Eacock, J. R., Defence Research Agency, UK; Foord, R., Defence Research Agency, UK; The Characterisation and Modification of Wakes from Lifting Vehicles in Fluids; Nov. 1996; 10p; In English; See also 19970014096; Original contains color illustrations; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Wake vortices of aircraft landing at Heathrow have been measured with a coherent laser radar. Analysis of the vortex velocity profiles from B747 aircraft shows a series of symmetrical dip or inversions on approach to the central core. Such inversions are not predicted theoretically and contrast with the uniformly increasing velocity profiles observed from other aircraft. Vortex trajectories may also be reconstructed; in one case a B747 vortex, after initial descent, returned to the glideslope with undiminished strength over a minute later.

WAKE VORTEX DECAY NEAR THE GROUND UNDER CONDITIONS OF STRONG STRATIFICATION AND WIND SHEAR

Rudis, R. P., Federal Aviation Administration, USA; Burnham, D. C., Scientific and Engineering Solutions, Inc., USA; Janota, P., System Resources Corp., USA; Nov. 1996; 10p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Using the tower fly-by method, decay measurements were made on wake vortices generated by B-727, B-757 and B-767 aircraft. In addition to a 60-meter instrumented tower, two remote sensing systems were deployed: (1) Laser Doppler Velocimeter (LDV) (high resolution vortex profiles at ranges of 40-200 meters) and (2) Monostatic Acoustic Vortex Sensing System (MAVSS) (lower resolution profiles up to 500 meters beyond the tower location). Typical early morning meteorology during the test period consisted of stratified drainage flows. Because of the persistent crosswind, the MAVSS gave the most complete vortex decay information. Meteorological conditions were measured by instruments on the tower and on a tether-

sonde. The analysis looked for statistical relationships between vortex lifetime and several meteorological parameters, treated independently. Due to the meteorological conditions of stratification, low turbulence and wind shear, the upwind vortex lasted longer than the downwind vortex; the circulation remained above 140 m(exp 2)/s for up to 125, 150 and 170 seconds for the B-727, B-757 and B-767, respectively. However, in every case, the crosswind was strong enough to sweep both wake vortices away from the generating location; in some cases the vortices traveled more than 500 meters laterally. Although these durations are much longer than the normally observed vortex lifetimes, they are related, according to the analysis, to strong crosswind shear coupled with low turbulence levels. While this long vortex migration at the observed strength levels might represent a potential vortex encounter hazard for operations on a downwind parallel runway, the drainage flow conditions which led to this unusual vortex behavior would be unlikely to occur at most airports.

WAKE TURBULENCE TRAINING AND REGULATION: AN INDUSTRY TEAM APPROACH

Carbaugh, David C., Boeing Commercial Airplane Co., USA; Forsythe, W. Douglas, Boeing Commercial Airplane Co., USA; Nov. 1996; 6p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper describes the development and content of the industry endorsed Wake Turbulence Training Aid and industry's input to regulators regarding wake turbulence efforts. The Wake Turbulence Training Aid is a safety document aimed at both pilots and air traffic controllers. The aid consists of a manual with pull out sections for easy use and a video of about 25 minutes in length. The reason for developing the aid is discussed. Increased traffic, mixed traffic, accidents and incidents, ASRS reports, and calls for action all culminated in needing training to step up to the need for more awareness and education for pilots and controllers. Who was involved in the development of the aid is discussed to highlight its international scope, as well as the time progression towards completion. The content of the aid is then discussed in detail. Lastly, the efforts of the industry team to make specific inputs to the FAA regarding efforts to reduce wake turbulence encounters and to improve safety is presented.

GROUND-BASED ANEMOMETER MEASUREMENTS OF WAKE VORTICES FROM LANDING AIRCRAFT AT AIRPORTS

Abramson, S., Federal Aviation Administration, USA; Burnham, D. C., Scientific and Engineering Solutions, Inc., USA; Nov. 1996; 8p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In 1994 an array of two-axis propeller anemometers was installed at 10-meter height under the approach to Runway 31 R at Kennedy Airport. Since the aircraft are typically 50 meters above the ground at the test location, the wake vortices rapidly descend toward the ground where they are readily detected and measured by the anemometers. In 1995 a similar installation was made on Runway 27 at the Memphis Airport. The ultimate goal of this study is to better understand when wake vortices remain in the flight path of following aircraft. The data collection system operates automatically and hence provides wake vortex data under all weather conditions and at all times of day and night with minimal cost. Real-time remote display of the vortex locations was implemented. The anemometers are augmented with additional weather sensors to provide meteorological data with greater detail than the standard surface weather observations. New processing methods for the anemometer data were developed to determine vortex height and strength in addition to the lateral position that was traditionally obtained from ground-based anemometers. The anemometer array is particularly appropriate for studying the interaction of wake vortices with the ground. It readily detects the secondary vortices detached from the boundary layer by the influence of the

primary wake vortices; these secondary vortices produce the well known vortex bouncing. Such secondary vortices have not been seen by any other sensing system.

EXPERIMENTAL ANALYSIS OF THE VORTEX WAKE STRUCTURE BEHIND A PROPELLER-WING CONFIGURATION

Veldhuis, L. L. M., Technische Hogeschool, Netherlands; Rentema, D. W. E., Technische Hogeschool, Netherlands; Nov. 1996; 18p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A flow field survey was performed with a 5-hole pressure probe at 1 chord length behind a propeller-wing configuration revealing important qualitative and quantitative information on the propeller dominated interactive flow field. The model, that consists of a low aspect ratio semi-span wing model combined with a 4 bladed tractor propeller, was tested at several low subsonic flow conditions in the Delft University Low Speed Windtunnel. The distribution of total pressure and axial vorticity show, besides the well-known spiral tip vortex, a strong deformation of the slipstream structure. The deformation of the vortex wake is strongly related to the spanwise lift distribution of the propeller/wing configuration which might be used as a starting point for prediction of vortex formation and decay. It also determines the magnitude of the overall induced drag and the deformation process therefore has implications for the proper modelling of slipstreams used within theoretical prediction codes for the analysis of airplane performance. To obtain quantitative information from the field data the theory of Betz and Maskell was applied to determine the lift, the profile drag and the induced drag for both the model with and without running propeller. Comparison of these results with external balance measurements shows a good agreement. The lift distributions which were compared with surface pressure measurements reveal that a considerable amount of swirl is left in the slipstream after passage of the wing; an important observation for future optimisation of propeller-wing configurations. In general the flow field survey with traversing 5 hole probe appears to be a powerful technique to better understand propeller/wing interactive flows.

FLOWFIELD OF A WING EMBEDDED IN THE WAKE OF A BURSTED VORTEX

Longo, J. M. A., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Orlowski, M., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Strohmeyer, D., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Nov. 1996; 8p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In the present paper the flowfield around a delta wing partially embedded in the wake of a bursted vortex is numerically studied at $M(\text{sub infinity}) = 0.4$. The simulation is carried out solving the Euler equations on two structured grids of about 2.3 million points and 300000 points respectively. Due to the lack of experimental results, special emphasis is put on the analysis of the effect of grid fineness on the wake-flow. The present investigation indicates that the spiraling flow of a vortex continues after breakdown with a swirl velocity comparable to that of a non-burst vortex generated at lower angles of attack and hence interference effects coming from its wake persist long downstream.

STABILITY OF MULTIPLE TRAILING-VORTEX PAIRS

Crouch, J. D., Boeing Commercial Airplane Co., USA; Nov. 1996; 8p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The stability of two vortex pairs is analyzed as a model for the vortex system generated by an aircraft in flaps-down configuration. The co-rotating vortices on the starboard and port sides tumble about one another as they propagate downward. This results in a time-periodic basic state. The instabilities are periodic along the axes of the vortices with wavelengths that are large compared to the size of the vortex cores. The results show symmetric instabilities that are linked to the long-wavelength Crow instability. In addition, new symmetric and antisymmetric instabilities are observed at shorter wavelengths. These instabilities have growth rates 60-100% greater than the Crow instability. The system of two vortex pairs also exhibits transient growth which can lead to growth factors of 5 or 10 in one fourth of the time required for the same growth due to instability.

The interaction between vortex pairs and well developed isotropic turbulence is studied by Direct Numerical Simulation. It is a model of the effect of natural environmental disturbances on airplane wakes. The nondimensional turbulence intensity ϵ is in the range (0 .02, 0.5), typical of airplanes. The most amplified wavelength of the Crow instability is placed within the inertial range of the turbulence, which is typical in the atmosphere and fits the theoretical setting of Tombach and Crow & Bate. The vorticity peaks in cross-flow planes are tracked to reveal the deformation of the vortices. In agreement with visual observations, the Crow instability dominates in weak turbulence, whereas chaotic deformations are seen in stronger turbulence. The average wavelength is about 27% shorter than the most amplified one. The beginning of destruction is identified with the first changes in the connectivity of the lines; identifying the end of destruction is more elusive. The wake lifespans overlap those from flight tests, laboratory tests, and the theory of Crow & Bate. However, in strong turbulence, theory and simulation both predict shorter average lifespans than the tests do. The scatter in lifespans is almost as large in simulations as in flight tests; thus, the intermittency of turbulence appears to explain the scatter even without any other differences in conditions. We conclude that the predictability of wake destruction by this mechanism is very poor.

The results of sinusoidal instability which were developed in a vortical gate composed of two turbulent vapor trails are presented. The results are consistent with the theories of linear instability developed by Crow. The effects of the density of the airflow, the limiting conditions, and the shape of the initial perturbation on the quality of the solution are studied.

To perform a stability analysis on an interesting flow field, an undisturbed quasi steady basic velocity profile of the concerned flow field must be provided. In case of wake vortices behind cruising aircraft, the velocity distribution within the vortices has to be evaluated as a function of the height coordinate z and the spanwise coordinate y . A three-dimensional vortex filament method was used to calculate the velocity field of the wake flow, because it is an efficient tool for flows consisting of large regions of vorticity. Vortex filament methods simulate such a flow field by discretizing the regions behind the aircraft wing which contain vorticity, and tracking this discretization in a Lagrangian reference frame. The velocity field behind the aircraft is determined kinematically from the given vorticity field and computed by an application of the Biot-Savart-law. Small perturbations are then superimposed on the given quasi steady base flow and this sum is then substituted into the governing equations. After a linearization process, two fourth order perturbation differential equations are found. They give rise to an eigenvalue problem with a complex eigenvalue S and eigenfunctions for the amplitudes of the disturbances.

The roll-up of the trailing vortex system behind a generic civil aircraft windtunnel model with extended flaps and slats is studied up to 5 wing spans downstream. A laser light sheet flow visualisation technique is used and detailed flow field measurements are made with a spanwise traversable rake with five-hole probes. The measurement results are compared against calculations with the 2D vorticity transport equation.

MEASUREMENTS IN VORTEX WAKES SHED BY CONVENTIONAL AND MODIFIED SUBSONIC AIRCRAFT

Rossow, Vernon J., NASA Ames Research Center, USA; Nov. 1996; 10p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

A theoretical and experimental program is underway at NASA Ames Research Center to first obtain a better understanding of the hazard posed by the vortex wakes of subsonic transports, and then to develop methods on how to modify the wake-generating aircraft in order to make the vortices less hazardous. This paper summarizes results obtained in the 80- by 120-Foot Wind Tunnel at NASA Ames Research Center on the characteristics of the vortex wakes that trail from 0.03 scale models of a B-747 and of a DC-10. Measurements are first described that were taken in the wakes with a hot-film anemometer probe, and with wings that range in size from 0.2 to 1.0 times the span of the wake generating models at downstream distances of 81 ft and 162 ft. behind the wake-generating model; i.e., at scale distances of 0.5 and 1.0 mile. The data are then used to evaluate the accuracy of a vortex-lattice method for prediction of the loads induced on following wings by vortex wakes.

The forced trailing vortex wake of a rectangular NACA 0012 airfoil with an aspect ratio of 8 is investigated experimentally. The experiments include limited five-hole probe measurements in the near wake in a wind tunnel and extensive DPIV measurements in the far wake in a town tank. Measurements are conducted on the natural wake and the forced wake at chord Reynolds numbers from 2×10^5 to 6×10^5 (exp 4). The wake is forced by axial jets located on each wing-tip injecting fluid into the vortex cores. The forcing is steady or pulsatile. Pulsatile forcing is varied from 1 Hz to 40 Hz and with the wing-tip jets in phase, out of phase, or one on/one off. Relevant parameters, including vortex separation, vorticity, circulation, and core size, are measured up to 1000 chord lengths behind the wing. Forcing increases both the separation of the vortex pair and the growth rate of the vortex core size. At low frequencies, these effects are monotonic with increasing forcing frequency. At high frequencies, the measurements suggest a complex response to forcing. Based on measurements and observations, some parameters of importance are suggested in exploring possible means of controlling the behavior of the vortex wake. The complexity of the problem dictates that any search for identifying practical solutions must be a concerted effort among experiments, analyses and numerics.

This paper presents three-dimensional direct numerical simulations of a vortex pair. Two types of computations are conducted. The first type considers a vortex pair placed in an homogeneous turbulent field. The phenomenon of interaction between the vortices and the turbulence is analyzed in details from two simulations calculated on a $135 \times 135 \times 135$ nodes mesh grid (one case with axial core velocity, the other without). The results show that the role of large and small turbulent eddies can be separated into two fairly independent mechanisms. The large structures are stretched by velocity gradients induced by the vortex pair. That leads to the formation of both tubes of vorticity spinning azimuthally around each vortex and associated axial velocity sheets. These turbulent structures cause a strong decrease of the maximal velocity and curvature of the vortices. These deformations of the vortex induced by the turbulence initiate an antisymmetric long-wave instability of the pair which will probably lead to the collapse of the vortices. Concurrently, the small structures can enhance the diffusion of the vorticity out of the vortex core. From this analysis and dimension considerations, the correct form for a model of decay of the vortices is derived. On the other hand, nine simulations on a $813 \times 813 \times 813$ nodes mesh grid are used to determine the sensibility of the results upon the random turbulent initial conditions. The second type of computations considers a vortex pair placed in a laminar flow field near the ground. This laminar flow is representative of a neutral surface boundary layer. The effect of variable crosswind shear is studied with the effect of an axial wind. A comparison between the two-dimensional and the three-

dimensional results shows that the main phenomenon is not modified but that the altitude of rebound depends on the three components of the wind.

DIRECT NUMERICAL SIMULATION OF THE BREAKDOWN OF AIRCRAFT WAKE VORTICES

Rennich, S. C., Stanford Univ., USA; Lele, S. K., Stanford Univ., USA; Nov. 1996; 10p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

An investigation is initiated that aims to improve the understanding of how disturbances to aircraft vortex wakes, applied at the wing, survive the roll-up process and eventually lead to destruction, or 'breakdown', of the wake. To efficiently perform this investigation, a numerical method is presented which accurately and efficiently computes flows in domains that are unbounded in two directions and periodic in the third, subject to the condition that vorticity is compactly distributed in the unbounded directions. This new code is used to compute the growth of symmetric disturbances on a pair of counter rotating columnar vortices. For high Reynolds number, the inviscid, linear vortex filament results of Crow (5) which predict the most unstable wavelength and its amplification rate, are reproduced well. From these computations an eigenfunction of the Crow instability as it exists in an evolving viscous vortex pair is extracted. The evolution of a perturbed plane wake due to an elliptically loaded wing is computed. It is observed that a perturbation of the correct wavelength rapidly evolves into the Crow instability and grows at approximately the predicted rate.

THE INVISCID MOTION OF A VORTEX PAIR IN A COMPRESSIBLE AND STRATIFIED ATMOSPHERE

Stuff, Roland, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Nov. 1996; 10p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The movement of an inviscid vortex pair in a compressible atmosphere including buoyancy effects is described by analytic solutions. The effects of compressibility are dealt with in an isentropic atmosphere. The work of compression done by the atmosphere on the vortex is entirely consumed by the isentropic change of the thermodynamic state of the vortex pair. The acceleration of the accompanying and apparent mass is given by the displacement of the two vortices towards each other. The effects of buoyancy are investigated by means of a two-dimensional, incompressible, inviscid vortex pair which is heavier than the ambient fluid. It turns out that the condition of pressure continuity across the separating streamline can be achieved only by assuming an increase in circulation of the two vortices. The mass accompanying the vortex pair under the effect of non-conservative forces converts a fraction of its gravity potential into an

increase of stagnation pressure. Both, the analytical formulas for compressibility and buoyancy, then, are combined to describe both effects simultaneously. Thus, inconsistencies of other papers are eliminated.

Experiments and numerical simulations have been performed to investigate the spiral breakdown of a wing tip vortex in flowfields of adverse axial pressure gradient. The basic idea was to stretch the transition domain between A and B by a reduction of the imposed pressure gradient. Embedding the vortex in a flowfield with only gradual axial retardation, a stretching could be achieved in both, experiment and calculation, giving some interesting insight into the mechanism of vortex breakdown. The appearance of reversed axial flow, upstream of the spiral, is identified as the distinctive feature of vortex breakdown, that must lead to the loss of axial symmetry and to an unsteady flow.

COMPUTATIONAL AND EXPERIMENTAL INVESTIGATION OF THE WAKES SHED FROM FLAPPING AIRFOILS AND THEIR WAKE INTERFERENCE/IMPINGEMENT CHARACTERISTICS

Dohring, C. M., Naval Postgraduate School, USA; Platzer, M. F., Naval Postgraduate School, USA; Jones, K. D., Naval Postgraduate School, USA; Tuncer, I. H., Naval Postgraduate School, USA; Nov. 1996; 10p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Computational and experimental water tunnel investigations of the wakes shed from flapping airfoils are described. It is shown that there exists a critical nondimensional plunge velocity above which the wake changes from a symmetric thrust-producing vortical structure to an asymmetric lift and thrust-producing one. Furthermore, it is found that the impingement of the wake generated by a flapping airfoil on a stationary airfoil produces a significant thrust augmentation on the flapping/stationary airfoil combination. Similarly, there exists a beneficial ground interference effect if the airfoil is flapping near a stationary wall. The experimental data are based on flow visualization using a two-color dye injection technique and laser-doppler velocimetry. The numerical results are obtained from an unsteady inviscid incompressible two-dimensional panel code and from a two-dimensional Navier-Stokes code. Comparisons between the experimental and numerical results show good agreement.

RECENT LABORATORY AND NUMERICAL TRAILING VORTEX STUDIES

Delisi, Donald P., Northwest Research Associates, Inc., USA; Greene, George C., NASA Langley Research Center, USA; Robins, Robert E., Northwest Research Associates, Inc., USA; Singh, Raminder, Indian Inst. of Tech., India; Nov. 1996; 10p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Results from two laboratory studies and two numerical studies are presented. In the first laboratory study, measurements of the strength of vortices from a three-dimensional (3-D) model wing are presented. The measurements follow the vortices as they evolve in time from a two-dimensional (2-D) line vortex pair to the development and migration of 3-D vortex rings. It is shown that the resulting vortex rings can contain up to 40 percent of the initial vortex circulation. Thus, the formation of vortex rings may not necessarily signal the end of the

wake hazard to following aircraft. In the second laboratory study, we present the results of an experiment which shows how the spanwise drag distribution affects wake-vortex evolution. In this experiment, we modified the spanwise drag distribution on a model wing while keeping the total lift and drag constant. The results show that adding drag on or near the centerline of the wing has a larger effect than adding drag at or near the wingtips. These measurements complement the results of NASA studies in the 1970s. In the first numerical study, results of 3-D numerical calculations are presented which show that the vortex Reynolds number has a significant influence on the evolution and migration of wake vortices. When the Reynolds number is large, 3-D vortex rings evolve from the initially 2-D line vortex pairs. These vortex rings then migrate vertically. When the Reynolds number is lower, the transition of vorticity from 2-D to 3-D is delayed. When the Reynolds number is very low, the vortices never transition to 3-D, and the vertical migration is significantly reduced. It is suggested that this effect may have been important in previous laboratory wake-evolution studies. A second numerical study shows the influence that vertical wind shear can have on trailing vortex evolution.

By means of a vortex-filament technique and large eddy simulations dynamics are discussed which control the distribution of the exhaust of a subsonic aircraft under cruising conditions from the nozzle exit to the distance where the trailing vortex pair starts to collapse into turbulence. Emphasis is first put on the method; second on the initial roll-up process and the phenomenon of 'non-entrainment' of exhaust into the vortex cores. Third, the role of turbulence on the onset of the wingtip-vortex decay is considered; thereby it is distinguished between background atmospheric turbulence and turbulence stemming from the boundary-layer around the aircraft.

This paper will present aerodynamic results of investigations of wrap around fin missile configurations. The investigations were carried out at Wright Laboratory's Armament Directorate, Eglin AFB, FL. The investigations have shown that instabilities exist in the form of an undamped side moment induced by the pitching motion of the missile, a roll moment at zero degrees angle-of-attack, and a roll moment reversal through Mach 1. This paper will also present data for alternative deployable fin designs.

At the end of a missile development, flight tests have to validate the overall missile performances. The flight tests are particularly used for the validation of the aerodynamic characteristics. After that, some improvements of the aerodynamic modeling or even adjustments of the aerodynamic design can be initiated. Simulations allow to limit

expensive flight tests to a minimal number needed to perfect the guidance and control functions embedded in the missile. The aerodynamic coefficients are not directly measured in flight, but computed from measured flight data. Some results obtained with a long range cruise missile are therefore presented. The comparison with wind tunnel test data are explained and are satisfactory.

The main motivation underlying this work is to develop a methodology by which the effect of aerodynamic estimation errors on flight simulation problems are investigated. A 'family' is defined as a predetermined class of similar missile configurations for which a reference aerodynamic data is available. The error is defined as the difference between the results of the 'available computational method' and the reference data. Then the statistical characteristics of the errors in the aerodynamic coefficients are determined assuming Gaussian probability distribution for the members of the 'family'. For a proposed missile configuration which fits to the 'family', the aerodynamic coefficients are first obtained using the 'available computational method'. Afterwards, the errors in these aerodynamic coefficients are estimated using the statistical characteristics determined above.

AERODYNAMICS OF THE ARMOR X7 UAV

deBredereode, V., Technical Univ. of Lisbon, Portugal; Jorge, P. A., Technical Univ. of Lisbon, Portugal; Marcelino, J. R., Technical Univ. of Lisbon, Portugal; Patraquim, R., Technical Univ. of Lisbon, Portugal; Nov. 1996; 11p; In English; See also 19970018626; Sponsored in part by PEDIP; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The paper reports the most significant aspects of the aerodynamic design and testing of a low speed UAV which is being developed in Portugal as a joint University/Industry project. Starting from a baseline configuration of the air-vehicle aimed at complying with mission requirements in terms of endurance and range, a parametric sensitivity study is carried out for defining the optimum lay-out of the lifting surfaces. The family of the wing aerofoils is selected from the Wortmann series and a new aerofoil is designed for the tip section. Predicted and wind-tunnel results for the fuselage and inner-wing panels are reported and discussed and an assessment of the aerodynamic behaviour of the whole configuration is made.

Lecture notes for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Capsule Aerothermodynamics' have been assembled in this report. Aerodynamic design aspects related to planetary probe and capsule configurations are covered, as well as critical phenomena occurring during the different regimes of flight. The impact of real gas and rarefaction on capsule aerothermodynamics, and in particular on forebody and wake flow, is addressed. The material

assembled in this report was prepared under the combined sponsorship of the AGARD Fluid Dynamics Panel, the Consultant and Exchange Program of AGARD, and the von Karman Institute (VKI) for Fluid Dynamics.

At present, on a world scale, different capsules and penetrators are being considered for planetary entry such as the Huygens probe to Titan, the Intermarsnet to Mars, and the Mercury orbiter probe to Venus. In addition conceptual studies for earth reentry are in progress for crew transport vehicles. Their geometries vary from low lift to drag ratio Apollo type to more advanced and complex bent biconic high lift to drag configurations. Because of the renewed interest in Capsule Aerothermodynamics, this course is organized to stimulate research in this field for young engineers as well as to update expertise for more experienced aerodynamicists. The course will cover all aerodynamic design aspects related to planetary probe and capsule configurations. Critical phenomena occurring during the different regimes of flight from the rarefied through the hypersonic, supersonic, transonic and subsonic portions of flight will be reviewed. The impact of real gas and rarefaction on capsule aerothermodynamics and in particular on forebody and wake flows will be addressed. In addition present day computational and experimental capabilities to assess radiation, blackout, ablation and the characterization of the dynamic derivatives will be discussed.

The impact of rarefaction on entry capsules and spacecraft aerothermodynamics is emphasized for various aeroassist missions. The capability of the direct simulation Monte Carlo (DSMC) method to simulate such flows is demonstrated through examples of validation studies and applications. Several space flight projects and ground-based experiments are reviewed for which rarefaction effects have significant effect on spacecraft performance or experimental measurements. This review clearly demonstrates the significant role that the DSMC method plays in characterizing such flows.

REAL GAS: CFD PREDICTION METHODOLOGY FLOW PHYSICS FOR ENTRY CAPSULE MISSION SCENARIOS

Deiwert, George S., NASA Ames Research Center, USA; May 1995; 10p; In English; See also 19970026365; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Mission and concept studies for space exploration are described for the purpose of identifying flow physics for entry capsule mission scenarios. These studies are a necessary precursor to the development and application of CFD prediction methodology for capsule aerothermodynamics. The scope of missions considered includes manned

and unmanned cislunar missions, missions to the minor planets, and missions to the major planets and other celestial objects in the solar system.

The flow behind the shock wave formed around objects which fly at hypervelocity behaves differently from that of a perfect gas. Molecules become vibrationally excited, dissociated, and ionized. The hot gas may emit or absorb radiation. When the atoms produced by dissociation reach the wall surface, chemical reactions, including recombination, may occur. The thermochemical phenomena of vibration, dissociation, ionization, surface chemical reaction, and radiation are referred to commonly as high-temperature real-gas phenomena. The phenomena cause changes in the dynamic behavior of the flow and the surface pressure and heat transfer distribution around the object. The character of a real gas is described by the internal degrees of freedom and state of constituent molecules; nitrogen and oxygen for air. The internal energy states, rotation, vibration and electronic, of the molecules are excited and, in the limit, the molecular bonds are exceeded and the gas dissociated into atomic and, possibly, ionic constituents. The process of energy transfer causing excitation, dissociation and recombination is a rate process controlled by particle collisions. Binary, two-body, collisions are sufficient to cause internal excitation, dissociation and ionization while three-body collisions are required to recombine the particles into molecular constituents. If the rates of energy transfer are fast with respect to the local fluid dynamic time scale the gas is in, or nearly in, equilibrium. If the energy transfer rates are very slow the gas can be described as frozen. In all other instances, wherein any of the energy exchange rates are comparable to the local fluid time scale, the gas will be thermally or chemically reacting and out of equilibrium. Real gas thermochemical nonequilibrium processes are important in the determination of aerodynamic heating; both convective (including wall catalytic effects) and radiative heating. To illustrate this we consider the hypervelocity flow over a bluff body typical of an atmospheric entry vehicle or an aerospace transfer vehicle (ASTV). The qualitative aspects of a hypersonic flow field over a bluff body are discussed in two parts, forebody and afterbody, with attention to which particular physical effects must be included in an analysis. This will indicate what type of numerical modeling will be adequate in each region of the flow. A bluff forebody flow field is dominated by the presence of the strong bow shock wave and the consequent heating, and chemical reaction of the gas. At high altitude hypersonic flight conditions the thermal excitation and chemical reaction of the gas occur slowly enough that a significant portion of the flow field is in a state of thermochemical nonequilibrium. A second important effect is the presence of the thick boundary layer along the forebody surface. In this region there are large thermal and chemical species gradients due to the interaction of the gas with the wall. Also at high altitudes the shock wave and the boundary layer may become so thick that they merge; in this case the entire shock layer is dominated by viscous effects.

BLUNT BODIES DYNAMIC DERIVATIVES

Baillon, M., Aerospatiale, France; May 1995; 28p; In English; See also 19970026365; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This document addresses the aerodynamic damping coefficients of capsules and planetary entry probes. First, the general item of dynamic coefficients will be described, and the specificity of large drag,

blunted shapes will be described. A tentative description of the dynamic instability of the capsule type shapes will be shown. This dynamic instability has strong consequences at system level, in the frame of the development phase of both capsules and planetary entry probes, which will then be depicted. The determination of the dynamic coefficients will be addressed, both by theoretical and experimental ways. Finally, the HUYGENS entry module case will be detailed.

RADIATIVE HEAT FLUX: THEORETICAL AND EXPERIMENTAL PREDICTIONS FOR TITAN ENTRY PROBE

Baillion, M., Aerospatiale, France; Taquin, G., Aerospatiale, France; May 1995; 30p; In English; See also 19970026365; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This document presents the rationale of radiative heat flux predictions which were performed in the frame of the HUYGENS probe project. Due to the particular nature of TITAN atmosphere, associated to the entry velocity of the probe, the radiative heat flux is almost half of the total heat flux. In the thermal protection design process, accurate radiative heat flux calculations are needed in order to design a secured environment for onboard experiments, while mass penalties of thermal protection must be avoided. This document describes the theoretical and experimental investigations of the radiative heat fluxes which were performed in the frame of the HUYGENS program.

AEROTHERMODYNAMIC REQUIREMENTS AND DESIGN OF THE HUYGENS PROBE

Baillion, M., Aerospatiale, France; May 1995; 28p; In English; See also 19970026365; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper presents the relationship between the main system requirements of the HUYGENS probe, derived either from mission analysis or from experiment related requirements, to the aerodynamics and aerothermodynamics studies. The first part of the document will present the main mission and experiment related requirements, as they are expressed at the very beginning of the project, and which are derived from the specificity of the mission, without any direct link with aerothermodynamics. The general system requirements of the HUYGENS probe, are the ones which are expressed by the customer ESA towards the industrial prime contractor Aerospatiale Space & Defense, and which correspond to the elementary requirements of feasibility of the mission, in terms of general objective: reach TITAN, survive a 7 years cruise in deep space, survive to the hypersonic entry in TITAN atmosphere. The second part will show how these very general requirements are translated in terms of aerothermodynamics requirements. The third part will show how these aerothermodynamics requirements are implemented in general aerothermodynamics studies and test plan, which has been actually performed in the frame of the HUYGENS project. The choice of the shapes, the Computational Fluid Dynamics (CFD) and test plan, the related CFD and wind tunnel specificity and difficulties are addressed. The need for characterisation of the convective and radiative heat fluxes in an unknown environment is shown. Finally very specific items like contamination and spin device are addressed.

EXTERNAL HYPERSONIC AERODYNAMICS: STATE-OF-THE-ART AND FUTURE PERSPECTIVE

Wendt, John F., Von Karman Inst. for Fluid Dynamics, Belgium; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 8p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

An overview is provided on the activities, conclusions and recommendations of AGARD Working Group 18. Four issues were defined and addressed; shock wave boundary layer interactions, transition, real-gas effects, and rarefied-flow effects. Three status reports were prepared on calibration procedures for high-enthalpy facilities, extrapolation of wind tunnel results to flight, and real-gas facilities. While considerable progress has been made in our understanding of external hypersonic flows through experiments in new facilities, advances in CFD, and improved modelling of complex phenomena, more efforts must be devoted to this area if the risks of failure or over-design are to be reduced to acceptable levels. Specifically, resources should be allocated to: a resolve facility, computational, and modelling deficiencies to accelerate the multiple facility/multiple computation strategy with standard models employed by Working Group 18.

AEROTHERMAL CHARACTERISTICS OF SHOCK/SHOCK INTERACTION REGIONS IN HYPERSONIC FLOWS

Holden, Michael S., Calspan-Buffalo Univ. Research Center, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 14p; In English; See also 19980018672; Contract(s)/Grant(s): SDIO84-93-C-0001; F49620-95-1-0292; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A review is presented of the aerothermal characteristics of regions of shock/shock interaction in hypersonic flow. Here, we discuss four aspects of the problem: (1) the requirements for accurate measurements in these flows; (2) the characteristics of shock/shock interaction regions in rarefied and laminar flows; (3) the aerothermal loads generated in transitional regions of shock/shock interaction; and (4) real-gas effects in regions of shock/shock interaction. The characteristics of shock/shock interaction regions and the influence of Mach number and Reynolds number on the heating loads developed in them are discussed. Correlations are presented together with the results of semi-empirical prediction methods to describe the aerothermal loads spanning the non-continuum to high Reynolds number flow regime. Some preliminary results are presented to demonstrate that the real-gas effects act to diffuse and lower the aerothermal loads relative to the ideal gas environment.

The paper reviews the growth and advances in computational capabilities for hypersonic applications over the period from the mid-1980's to the present day. The current status of the code development issues such as surface and field grid generation, algorithms, physical and chemical modeling, and validation is provided. A brief description of some of the major codes being used at NASA Langley Research Center for hypersonic continuum and rarefied flows is provided, along with their capabilities and deficiencies. A number of

application examples are presented, and future areas of research to enhance accuracy, reliability, efficiency, and robustness of computational codes are discussed.

COMPUTATIONAL SIMULATION OF HYPERSONIC EXTERNAL FLOW: STATUS OF CFD IN EUROPE

Kordulla, W., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Morice, Ph., Office National d'Etudes et de Recherches Aerospatiales, France; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 16p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper attempts to review the status of computational simulation of hypersonic flow achieved in Europe (except for the work performed in the countries of the former Soviet Union) within the past five to ten years. It is shown that national and concerted European efforts fostered the development of CFD in intimate combination with experimental work, in particular for validation purposes. It is believed that the state achieved, although not yet perfect, will be of tremendous help for the design process of an operational vehicle.

For some 50 years, man has flown, very successfully, in and through the hypersonic flow regime up to Mach Number 35 and beyond with very few "surprises." In general, hypersonic vehicles have performed successfully with good-to-excellent comparisons between flight, ground facility extrapolations and computations being the norm. A consistent and glaring shortfall to date is in the boundary layer transition arena, due primarily to the dominance for flight vehicles of roughness induced transition where the roughness characteristics are extremely vehicle specific and dictated by either vehicle operational exigencies such as antennas, handling plugs, and field joints, etc. or characteristics of the thermal protection system. Emerging shortfalls for future systems which require research flight tests include transition and air-breathing propulsion-related technology for both cruise and space access. Specific flight test recommendations include "systems

demonstrations" for various air-breathing propulsion options and efforts to correct a pervasive lack of adequate analysis of the existing, and very expensive to replicate, hypersonic flight data base.

AEROTHERMODYNAMICS AND PROPULSION INTEGRATION: SYNTHESIS OF THE AGARD-FDP-VKI SPECIAL COURSE, APRIL 15-19, 1996

Hirschel, E. H., Daimler-Benz Aerospace A.G., Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 8p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The AGARD-FDP-VKI Special Course "Aerothermodynamics and Propulsion Integration for Hypersonic Vehicles" dealt with basic topics of aerothermodynamics, with configurational aerothermodynamic of re-entry vehicles, airbreathing vehicles and missiles, and with inlet and aerothermodynamic airframe/propulsion integration of RAM and SCRAM propelled vehicles. In this paper the contributions, which were devoted to aerothermodynamic airframe/propulsion integration in the widest sense, are synthesized. After a general discussion of the problem, the main topics forebody, inlet, nozzle/afterbody, the whole vehicle, are detailed, partly with illustrating examples. Finally the potentials and deficits of simulation means are considered.

NON-LINEAR NONSTEADY EFFECTS IN THE HYDRODYNAMICS OF THE OSCILLATING WING

Dovgij, S. A., Academy of Sciences of the Ukraine, Ukraine; Feb. 1998; 9p; In English; See also 19980020532; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The article presents the analysis of the nonsteady hydroaerodynamic characteristics of the oscillating wing with the infinite span performing the function of the propulsor. The results are received for the non-linear theory by means of the discrete vortices method. The comparison of data is conducted based on the quasisteady approach, linear and non-linear theories. It is also noted that for those modes of the wing motion which are able to simulate the operation of the wing propulsors of hydrobionts valid results can be given with the help of the nonsteady theory only.

FOREBODY VORTEX CONTROL

Walchli, Lawrence A., Wright Lab., USA; Moorhouse, David J., Wright Lab., USA; Advances in Flight Testing; Dec. 1997; 18p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Much attention has been focussed in recent years on tactical maneuvering in post-stall flight. Such programs as the X31, VISTA/MATV, and the X-29A have established that tactical supermaneuverability at very high Angles of Attack (AOA) is a potent offensive weapon provided that the adversary can be enticed into close-in combat. Never before have requirements for integrating the pilot and aircraft been so important. The aircraft must have robust control authority in all axes, plenty of excess thrust, and pilot-friendly controls which allow him to fly to the limits of both his and the aircraft capability. Modern fighter aircraft operating above about 25 deg. AOA encounter a destabilizing phenomena caused by the complex three-dimensional separated vortical flowfield surrounding it. It is in this same region of flight that the aircraft wings and fuselage begin blanking the rudder, resulting in both degraded directional stability and control authority. Hence, two requirements emerge; increase directional stability and increase directional control authority. Thrust vectoring has been demonstrated as a means to increase control authority at all angles of attack. A potential way to increase directional stability could be by controlling the

02 AERODYNAMICS

forebody vortex flow. The primary object of this paper is to document an attempt to increase the directional stability of an F16 aircraft at all angles of attack into the post-stall regime. A wind tunnel test program had previously shown beneficial effects of forebody chines; additional testing provided stability and control data to support a flight test program. Flight tests were conducted with and without chines as a small adjunct to a program investigating thrust vectoring to very high angles of attack, the F-16 VISTA/MATV program. Specific maneuvers up to $C_{(sub\ Lmax)}$ (and beyond) were assessed to determine the major effects of forebody chines, although parameter identification was not an objective of the program. This paper describes the results of this effort.

CALCULATED VISCOUS AND SCALE EFFECTS ON TRANSONIC AEROELASTICITY

Edwards, John W., NASA Langley Research Center, USA; Mar. 1998; 11p; In English; See also 19980202469; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A viscous-inviscid interactive coupling method is used for the computation of unsteady transonic flows. A lagextraintment integral boundary layer method is used with a transonic small disturbance potential code to compute the transonic aeroelastic response for two wing flutter models. By varying the modeled length scale, viscous effects may be studied as the Reynolds number per reference chord-length varies. Appropriate variation of modeled frequencies and generalized masses then allows comparison of responses for varying scales or Reynolds number. Two wing planforms are studied: one a four percent thick swept wing and the other a typical business jet wing. Calculations for both wings show limit cycle oscillations at transonic speeds in the vicinity of minimum flutter speed indices.

We present the evolution of the use of CFD methods within our system of aeroelastic analysis (ELFINI). We started from a tool founded on the coupling of a structural Finite Element (FE) model and of an aerodynamic model, based on linear potential theory, empirically calibrated (mainly from flight tests). The linear character of these models allows a very efficient organization of inexpensive calculations (notions of load basis and of aerodynamic basis), sweeping of all of the flight configurations (Mach, altitudes, maneuvers, mass and external store configurations). Presently, keeping the same organization, we use an Euler FE method for the effects of initial shapes and of rigid motions. Now we push our developments in two main directions: non linear methods of direct static and dynamic coupling with aerodynamic models by non linear potential methods and mainly by steady and unsteady FE Euler methods; and linearized Euler methods in the neighborhood of previous non linear static aeroelastic solutions. In conclusion, we evoke the main features of our future organization of aeroelasticity analysis which will be more accurate while remaining affordable.

APPLICATION OF THE ENS3DAE EULER/NAVIER-STOKES AEROELASTIC METHOD

Schuster, David M., NASA Langley Research Center, USA; Beran, Philip S., Air Force Inst. of Tech., USA; Huttsett, Lawrence J., Air Force Research Lab., USA; Numerical Unsteady Aerodynamic and Aero-

elastic Simulation; Mar. 1998; 11p; In English; See also 19980202469 Contract(s)/Grant(s): F33615-95-D-3214; AF Proj. 0003; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper discusses recent applications of the ENS3DAE computational aeroelasticity method. In particular, it describes aeroelastic and unsteady aerodynamics calculations performed on wings with trailing edge control surfaces. These simulations include the investigation of control reversal for a structurally flexible wing with a deflected control surface, and a static and dynamic analysis of a rigid wing with an oscillating control surface. The two sets of calculations were performed independently on different wings using different grid topologies. The control reversal simulation represents an inviscid Euler static aeroelastic analysis of a thin wing with a rectangular planform. The geometry of this wing makes it suitable for computations using more approximate, inviscid aerodynamics methods. Thus, the results of the present Euler computations are compared with numerical data generated by a validated computational aeroelasticity code which uses a simpler aerodynamic formulation. The second illustrated case involves the simulation of a significantly more complex flowfield and the static and dynamic analyses of this geometry were performed using the viscous Navier-Stokes equation option in ENS3DAE. Results of both the steady and unsteady calculations on this wing are compared with existing experimental data.

AERODYNAMICS FOR ELASTICALLY OSCILLATING WINGS USING THE VIRTUAL GRID DEFORMATION METHOD

Wegner, W., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Mar. 1998; 12p; In English; See also 19980202469; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A new, efficient, and precise calculation method for unsteady aerodynamics is presented in this paper. It is called the "virtual grid deformation" method. The time-dependent grid deformation is observed virtually and without restriction, meaning that this method is also valid for high deflections and large amplitudes, respectively. This method is applicable to the conservation laws of fluid flows which are solved by a finite volume scheme and by a time-stepping procedure. Numerical results of a standard wing in steady and unsteady flow are compared with available measurements.

APPLICATION OF LINEARIZED EULER EQUATIONS TO THE ESTIMATION OF FLOTATION APPLICATION DES EQUATIONS D'EULER LINEARISEES A LA PREVISION DU FLOTTEMENT

Mortchalewicz, G. D., Office National d'Etudes et de Recherches Aeronautiques, France; Numerical Unsteady Aerodynamic and Aeroelastic Simulation; Mar. 1998; 8p; Translated in English by Schreiber; In French; See also 19980202469; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The use of linearized Euler equations in the context of harmonic excitations of structural modes makes it possible to calculate the aeroelastic forces in the frequency field at a reduced calculation cost which is well below the cost obtained by the classical method of time simulation using the Euler equations. Numerical examples make it possible to illustrate this approach.

In the past few years, great strides have been made in the analytical prediction of nonlinear flows using computational fluid dynamics (CFD). Coupled with the exponential growth in computer power, this has made it possible to analytically predict the unsteady aerodynamics and aeroelastic motion of complex configurations in nonlinear flow regimes. Unfortunately, these analyses are extremely costly due to the vast amount of computational effort required to compute the requisite time histories. This computational expense limits the use of these nonlinear aeroelastic tools to special cases, and eliminates them from consideration whenever a large number of conditions must be evaluated. Due to this high cost, the aerodynamic tools used in certification analysis and aeroelastic design optimization are usually based on linear lifting surface theory or panel methods. This paper presents a method to bridge this gap, so that the improved accuracy of the expensive nonlinear aerodynamic/aeroelastic methods can be injected into the economical production-type aeroelastic analyses through corrections to the linear aerodynamics. In contrast to techniques based on multiplicative correction factors, the present technique corrects the linear aerodynamics by removing a component of the pressure distribution from the linear theory, and replacing it with a component computed with a nonlinear method using a concept called "local equivalence." This allows a small number of nonlinear analyses to be applied to a large number of aeroelastic analyses. The technique is equally applicable to steady and unsteady aerodynamics. The formulation is such that, if available, steady or unsteady wind tunnel data can also be used in aeroelastic analysis and optimization. The scope of the paper is limited to comparing the results of corrected linear aerodynamics to the available nonlinear data, since many comparisons between nonlinear simulations and experiment are available in the literature. An application of the current technique to the flutter analysis of the AGARD 445.6 wing is shown, along with correlations between direct nonlinear flutter simulations and flutter solutions with corrected aerodynamics.

Flutter characteristics and results of aeroelastic time response analyses of NACA64010 airfoils oscillating in transonic flow are presented. These solutions were obtained by a newly developed two-dimensional aeroelastic simulation code which is designed in such a manner that the flow and the structure can be modelled independently by using the so-called domain decomposition approach. The coupled field problem is then effectively solved in the time domain by applying a partitioned solution procedure in which the fluid and the structural solvers are executed in an alternating fashion and exchange interface data only at certain time steps. In this study the prediction of the flow field around airfoils in arbitrary motion is based on the solution of the unsteady Euler equations. The structure might either be modelled as a rigid body system or as a more realistic flexible configuration. In this context, the finite element method is used to model elastic effects in the chordwise direction of a typical wing section, thus accounting for more general motions of the airfoil including the fluid structure interaction boundary. The underlying theory is briefly outlined and results are presented for several aeroelastic test cases of varying complexity in the structural model. Both cases with and without control surface are dealt with and the effect of flexibility on the transonic aeroelastic stability behavior is investigated.

The development of computational aerodynamic and aeroelastic simulation codes is steadily making progress. Nevertheless these codes are only modestly being accepted by the end-users in industry and other agencies in charge of flutter clearance or aeroelastic responses, in general. Various shortcomings of the current codes can be named which cause the reserve of the end-users. One of them is often unacceptable amount of manpower required for pre- and post-processing. NLR is developing a numerical aeroelastic simulation environment for applications to civil and fighter-type aircraft, of which a pilot version is in operation. Special attention has been given to the design of user friendly pre and postprocessing. The paper will discuss the motivation of an aeroelastic simulation environment, the status of the NLR Aeroelastic SIMulation system, the current research activities, the pre and postprocessing and future research activities. Several applications will be shown, demonstrating the use to both civil and fighter-type aircraft.

HIGH INCIDENCE UNSTEADY AERODYNAMICS FOR AEROSERVOELASTIC PREDICTIONS

Luber, W., Daimler-Benz Aerospace A.G., Germany; Becker, J., Daimler-Benz Aerospace A.G., Germany; Numerical Unsteady Aerodynamic and Aeroelastic Simulation; Mar. 1998; 16p; In English; See also 19980202469; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The aeroservoelastic stability of a fighter type aircraft is investigated at high angle of attack. The effects of non-linear, incidence dependent unsteady aerodynamic forces of elastic modes and of control surface deflections on the structural coupling are demonstrated for low and high subsonic speeds for different incidences. The difference of open loop frequency response functions calculated with linear and with high angle of attack unsteady aerodynamics documents the necessity of introduction of high incidence effects for aeroservoelastic stability calculations. Non-linear effects are introduced using unsteady pressures of windtunnel experiments on an oscillation model by correcting of theoretical pressures.

A UNIFIED UNSTEADY AERODYNAMIC MODULE FOR AEROELASTIC AND MDO APPLICATIONS

Chen, P. C., ZONA Technology, Inc., USA; Sarhaddi, d., ZONA Technology, Inc., USA; Liu, D. D., Arizona State Univ., USA; Mar. 1998; 14p; In English; See also 19980202469; Sponsored in part by Air force STTR.; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Recent advances in the lifting surface methods are attributed to the possible generalization of the Aerodynamic Influence Coefficient (AIC) method to the Transonic and Hypersonic flight regimes. Thus a unified AIC (UAIC) approach has been developed for aeroelastic/MDO applications in the complete Mach number range. A typical CFD method usually requires CFD/CSD interfacing in a time-domain aeroelastic analysis, while additional grid generation effort is needed in each MDO design cycle. The former procedure is still underdeveloped and the latter could be costly. Free from these procedures, the present UAIC is fully compatible with classical linear aeroelastic matrix equa-

tions. Thus, the UAIC approach as an unsteady aerodynamic module can be readily integrated with current standard FEM systems or into a MDO environment, practiced by aerospace industries. Specifically, the present module consists of four major unsteady aerodynamic codes which jointly cover all flight regimes, thereby rendering the module unified for all Mach numbers. First, the capability of the present aerodynamic module will be discussed. Second, the seamless integration of the present aero module with a MDO software ASTROS is properly defined. Third, cases studied for the validation of the integrated aerodynamic module will be presented. These include: supersonic analysis of a swept untapered wing, a fighter wing with transonic flutter constraint and a rectangular wing in roll with control surface reversal. Finally, we will present our concept of computational aeroelasticity in terms of Aeroelasticity Modeling Methodology (AIC methods) and Aeroelasticity Simulation Methodology (CFD methods) from the standpoint of industrial application. We believe that these two methodologies, if their practices follow the proposed global strategy, could compliment each other in achieving further computational expediency and with wider applicability.

Unsteady aerodynamics plays a vital role in the design of an aircraft. Already in the initial phase it is necessary to have reliable estimates of flutter boundaries and to supply information for control system software and hardware. Thus speed and accuracy of unsteady aerodynamic computation are required. In practice, it is natural to depend mainly on computations based on linear theory. There are situations where speed of computation and accuracy are contradictory, and then one must resort to previous experience and correction strategies. The elastic modern aircraft is becoming more and more aero-servo-elastic. The quality of simulation of the numerous feedback mechanisms is highly dependent on the accuracy of control surface aerodynamics. Moreover, the frequent application of multi-disciplinary optimization puts strong new demands on unsteady aerodynamic accuracy. In this paper, we will show examples of validating experiments and computations, and discuss applications of classical and new methods for real civil and military aircraft.

The prospect for useful measurements of airplane flow-field properties are reviewed. Early experience in flow-field measurements at Boeing is described, as are the requirements for quantitative flow-field surveys in industrial wind tunnels. Recent examples of quantitative flow-field measurements of lift and drag distributions in subsonic and transonic wind tunnels are presented. A new invention, called the Flying Strut, is introduced as a practical system for flow-field surveys in large wind tunnels and in flight.

The development of a high-speed, phase-locked, realtime, point diffraction interferometry system for quantitative imaging unsteady separated flows is described. The system enables recording of up to 224 interferograms of the dynamic stall flow over an oscillating airfoil using a drum camera at rates of up to 40 KHz controlled by custom designed electronic interlocking circuitry. Several thousand interferograms of the flow have been obtained using this system. A comprehensive image analysis package has been developed for automatic processing of this large number of images. The software has been specifically tuned to address the special characteristics of airfoil flow interferograms. Examples of images obtained using the standard and the high-speed interferometry techniques are presented along with a demonstration of the image processing routine's ability to resolve the fine details present in these images.

The increase in the PSP measurement accuracy in wind tunnels is related first of all to the application of the two-component PSP technology. Besides the active luminophor the luminescence of which depends on pressure, the two-component PSP formulation also contains an additional luminophor. The simultaneous measurement of the luminescence intensities of the active luminophor and the additional luminophor makes it possible to avoid numerous difficulties characteristic of the one-component PSP technology. Consideration is given to some processes affecting the two-component PSP measurement accuracy. The transonic wind tunnel investigations of the two-component PSP are presented. Also, the first results of investigating the possibility of applying PSP pressure measurements to the helicopter rotor blade using the two-component PSP are given.

Pressure sensitive paint (PSP) is a technology of major interest to wind tunnel operators. As part of the cooperation programme between ONERA and TsAGI an evaluation test of the optical pressure measurement system developed by TsAGI was performed in the tran-

sonic test section of the S2MA wind tunnel at the Modane centre. The tests were carried out on an Airbus model loaned by Aerospatiale. The left wing was instrumented with 240 pressure taps, the right wing was covered by a two-component PSP, developed by the Russian firm OPTROD. Experimental set-up, characteristics of the two component paint and data processing are described. Comparisons between results from conventional and PSP measurements are presented, and the effects of incidence, Mach number, pressure and temperature are discussed.

Optical pressure measurements have been made on a NACA 0012 airfoil coated with Pressure Sensitive Paint (PSP) at very low flow speeds (less than 50 m/s). Angle of attack was limited to 5 deg. for most measurements. Effects of temperature gradients and mis-registration errors on PSP response have been established and minimized by reducing measurement error caused by these effects. PSP sensitivity has been enhanced. Acceptable aerodynamic data at flow speeds down to 20 m/s have been obtained and valid pressure paint response was observed down to 10 m/s. Measurement errors (in terms of pressure and pressure coefficient) using PSP with pressure taps as a reference are provided for the range of flow speeds from 50 m/s to 10 m/s.

Only recently have large amounts of model deformation data been acquired in NASA wind tunnels. This acquisition of model deformation data was made possible by the development of an automated video photogrammetric system to measure the changes in wing twist and bending under aerodynamic load. The measurement technique is based upon a single view photogrammetric determination of two dimensional coordinates of wing targets with a fixed third dimensional coordinate, namely the spanwise location. A major consideration in the development of the measurement system was that use of the technique must not appreciably reduce wind tunnel productivity. The measurement technique has been used successfully for a number of tests at four large production wind tunnels at NASA and a dedicated system is nearing completion for a fifth facility. These facilities are the National Transonic Facility, the Transonic Dynamics Tunnel, and the Unitary Plan Wind Tunnel at NASA Langley, and the 12-FT Pressure Tunnel at NASA Ames. A dedicated system for the Langley 16-Foot Transonic Tunnel is scheduled to be used for the first time for a test in September. The advantages, limitations, and strategy of the technique as currently used in NASA wind tunnels are presented. Model deformation data are presented which illustrate the value of these measurements. Plans for further enhancements to the technique are presented.

Microelectromechanical systems (MEMS) embodies the integration of sensors, actuators, and electronics on a single substrate using integrated circuit fabrication techniques and compatible bulk and surface micromachining processes. Silicon and its derivatives form the material base for the MEMS technology. MEMS devices, including microsensors and microactuators, are attractive because they can be made small (characteristic dimension about 100 microns), be produced in large numbers with uniform performance, include electronics for high performance and sophisticated functionality, and be inexpensive. For aerodynamic measurements, it is preferred that sensors be small so as to approximate measurement at a point, and in fact, MEMS pressure sensors, wall shear-stress sensors, heat flux sensors and micromachined hot wires are nearing application. For the envisioned application to wind tunnel models, MEMS sensors can be placed on the surface or in very shallow grooves. MEMS devices have often been fabricated on stiff, flat silicon substrates, about 0.5 mm thick, and therefore were not easily mounted on curved surfaces. However, flexible substrates are now available and heat-flux sensor arrays have been wrapped around a curved turbine blade. Electrical leads can also be built into the flexible substrate. Thus MEMS instrumented wind tunnel models do not require deep spanwise grooves for tubes and leads that compromise the strength of conventionally instrumented models. With MEMS, even the electrical leads can potentially be eliminated if telemetry of the signals to an appropriate receiver can be implemented. While semiconductor silicon is well known for its electronic properties, it is also an excellent mechanical material for MEMS applications. However, silicon electronics are limited to operations below about 200 C, and silicon's mechanical properties start to diminish above 400 C. In recent years, silicon carbide (SiC) has emerged as the leading material candidate for applications in high temperature environments and can be used for high-temperature MEMS applications. With SiC, diodes and more complex electronics have been shown to operate to about 600 C, while the mechanical properties of SiC are maintained to much higher temperatures. Even when MEMS devices show benefits in the laboratory, there are many packaging challenges for any aeronautics application. Incorporating MEMS into these applications requires new approaches to packaging that goes beyond traditional integrated circuit (IC) packaging technologies. MEMS must interact mechanically, as well as electrically with their environment, making most traditional chip packaging and mounting techniques inadequate. Wind tunnels operate over wide temperature ranges in an environment that is far from being a 'clean-room.' In flight, aircraft are exposed to natural elements (e.g. rain, sun, ice, insects and dirt) and operational interferences (e.g. cleaning and deicing fluids, and maintenance crews). In propulsion systems applications, MEMS devices will have to operate in environments containing gases with very high temperatures, abrasive particles and combustion products. Hence deployment and packaging that maintains the integrity of the MEMS system is crucial. This paper presents an overview of MEMS fabrication and materials, descriptions of available sensors with more details on those being developed in our laboratories, and a discussion of sensor deployment options for wind tunnel and flight applications.

03 AIR TRANSPORTATION AND SAFETY

This AGARDograph has been compiled by an international team of wind tunnel wall correction experts. The state of the art in wall corrections is presented with special emphasis given to the description of modern methods based on Computational Fluid Dynamics (CFD). Topics covered include: Open Test Sections, Closed Test Sections, Ventilated Test Sections, Boundary Measurement Methods, Transonic Wall Interference, Bluff Body Corrections, Adaptive Walls, Panel Methods, and CFD Methods.

The paper reviews a combined numerical and experimental activity on the Shuttle Orbiter, first performed at NASA Langley within the Orbiter Experiment (OEX) and subsequently at ESA, as part of the AGARD FDP WG 18 activities. The study at Langley was undertaken to resolve the pitch up anomaly observed during the entry of the first flight of the Shuttle Orbiter. The present paper will focus on real gas effects on aerodynamics and not on heating. The facilities used at NASA Langley were the 15-in. Mach 6, the 20-in. Mach 6, the 31-in. Mach 10 and the 20-in. Mach 6 CF4 facility. The paper focuses on the high Mach, high altitude portion of the first entry of the Shuttle where the vehicle exhibited a nose-up pitching moment relative to pre-flight prediction of $(\Delta C_{\text{sub}} m) = 0.03$. In order to study the relative contribution of compressibility, viscous interaction and real gas effects on basic body pitching moment and flap efficiency, an experimental study was undertaken to examine the effects of Mach, Reynolds and ratio of specific heats at NASA. At high Mach, a decrease of gamma occurs in the shock layer due to high temperature effects. The primary effect of this lower specific heat ratio is a decrease of the pressure on the aft windward expansion surface of the Orbiter causing the nose-up pitching moment. Testing in the heavy gas, Mach 6 CF4 tunnel, gave a good simulation of high temperature effects. The facilities used at ESA were the 1m Mach 10 at ONERA Modane, the 0.7 m hot shot F4 at ONERA Le Fauga and the 0.88 m piston driven shock tube HEG at DLR Goettingen. Encouraging good force measurements were obtained in the F4 facility on the Orbiter configuration. Testing of the same model in the perfect gas Mach 10 S4 Modane facility was performed so as to have "reference" conditions. When one compares the F4 and S4 test results, the data suggests that the Orbiter "pitch up" is due to real gas effects. In addition, pressure measurements, performed on the aft portion of the windward side of the Halis configuration in HEG and F4, confirm that the pitch up is mainly attributed to a reduction of pressure due to a local decrease in gamma.

This chapter provides an overview of the current ground-based aerothermodynamic testing capabilities in Western Europe and the USA. The focus is on facilities capable of producing real-gas effects (dissociation, ionization, and thermochemical nonequilibrium) pertinent to the study of atmospheric flight in the Mach number range of 5 < M < 50. Perceived mission needs of interest to the Americans and Western Europeans are described where such real-gas flows are important. The role of Computational Fluid Dynamics (CFD) in modern ground testing is discussed, and the capabilities of selected American and European real-gas facilities are described. An update on the current instrumentation in aerothermodynamic testing is also outlined. Comments are made regarding the use of new facilities which have been brought on line during the past 3-5 years. Finally, future needs for aerothermodynamic testing, including instrumentation, are discussed and recommendations for implementation are reported.

Instability of the pilot/airframe combination has been a problem of manned flight. Rapid advances made in aviation following World War 2 greatly increased the incidence of PIO problems and the amount of research and development work aimed at understanding and mitigating these difficulties. Criteria and requirements were developed to be used in design to obtain satisfactory PIO qualities, but, in spite of all this work and the great flexibility in available modern control design technologies, PIO problems still often occur with new aircraft. It is clear that a universal solution of the PIO problem still evades the engineering community. The cost of these problems financially and in program delay is significant. This AGARD Flight Mechanics Workshop summary report contains presentations and discussions that aim toward the elimination and avoidance of PIO's by increasing the knowledge of PIO's and the problems associated with them.

PIO: A HISTORICAL PERSPECTIVE

Mcruer, Duane T., Systems Technology, Inc., USA; Smith, R. E., NASA Hugh L. Dryden Flight Research Facility, USA; Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations; Feb 1, 1995, 4 p; In English; See also 19950024640; Copyright; Avail: CASI; A01, Hardcopy; A02, Microfiche

These problems relating to Pilot Induced Oscillations have manifested themselves since the earliest days of manned flight. The earliest recorded examples of PIO date back to the Wright brothers first aircraft. The earliest filmed records date back to just prior to World War 2, with the XB-19 aircraft which suffered a pitch PIO just prior to touchdown. Four classes of PIO have been identified, into which all of the known incidents can be grouped. These are: (1) Essentially Single Axis, Extended Rigid Body Effective Vehicle Dynamics; (2) Essentially Single Axis, Extended Rigid Body with Significant Feel-System Manipulator Mechanical Control Elements; (3) Multiple Axis, Extended Rigid Body Effective Vehicle Dynamics; and (4) PIO's Involving Higher Frequency Modes.

THE PROCESS FOR ADDRESSING THE CHALLENGES OF
AIRCRAFT PILOT COUPLING

Aharrah, Ralph, NASA, USA; Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations; Feb 1, 1995, 3 p; In English; See also 19950024640; Copyright; Avail: CASI; A01, Hardcopy; A02, Microfiche

The term 'Pilot Induced Oscillation' is misleading in that it places an undue emphasis on the role of the pilot in the process. Clearly, the phenomenon cannot occur in the absence of the pilot, but the term PIO suggests that the pilot is in some way responsible for the occurrence. He is not. The phenomenon may be better described by the title 'Aircraft-Pilot Coupling', or A-PC. This may be considered to better describe what is actually occurring when the pilot is trying to perform his normal function, i.e., that of controlling the aircraft which he is flying. For a designer, the objective should be to ensure that there is no possibility of A-PC occurring. Associated with this, the goal should also be to achieve Level 1 handling qualities. The key is to understand the Process involved in design and test and to ensure that this is exercised to achieve the objective. This has to be set alongside the management goals of better, faster and cheaper, in order that the manufacturer can remain competitive in the market.

Comparison of the handling characteristics of a Porsche with those expected from a modern combat type aircraft indicate that we accept significantly poorer handling performance with the aircraft than we would with a high performance road vehicle. The work which led to the evolution of the Smith-Geddes criteria stems from work performed for the USAF in relation to the F-15 aircraft. The logic that arrived at the criteria stemmed from a belief that the existing handling qualities criteria were inadequate for assessing the Pilot Induced Oscillation (PIO) susceptibility of an aircraft, and that the only successful way to test for this was to use the methods of Handling Qualities During Tracking (HQDT). The work which was performed was offered for the update of Mil 1797, but was not incorporated. This presentation concentrated on the understanding of PIO and the process by which it originates, using a simple model to demonstrate the characteristics which are inherent. The presentation also provided an explanation of the Smith-Geddes criteria, without resorting to the detail of the theories which support the criteria. The major thrust relates to the application to the assessment of PIO susceptibility and includes a commentary on the state of the control law development, together with the associated flight test technology.

Eighteen years after the Tornado PIO (Pilot induced Oscillation) was successfully resolved, it seems inexplicable that similar PIO problems can still occur. For whatever reason, current formal methods are not working. The Vista F-16 is a powerful tool which should be put to use in establishing a universally acceptable set of criteria for the prevention of PIO by design. It should do this by determining the PIO qualities of a sufficiently wide range of linear and non-linear dynamic qualities, both in pitch and in roll, to establish a customer-defined set of Level boundary limits on whatever parameters are found best to

quantify PIO. Only by doing this will it be possible to resolve the claims of the many competing criteria and guarantee a PIO-free future for all. It is not particularly difficult to identify the means.

The main theme of this presentation, is that of relating the handling qualities issues, and specifically the PIO, to aircraft safety. It is essential that the programme managers recognize that PIO is safety critical in that it is loss of control, and that when it is encountered, it is as dangerous as a structural failure of the airframe.

The time delay which arises due to rate limiting in a control system has been identified as a contributing factor to the occurrence of pilot induced oscillations (PIO's). Recent discussions concerning PIO prevention measures have proposed the elimination of this time delay through an alternate control scheme. In response to this proposal, the SCARLET (Saturated Command and Rate Limited Elevator Time delay) project was initiated in order to study the effects of both the time delay and the elimination scheme on the handling qualities of a contemporary fly-by-wire aircraft. A flight experiment was carried out in 1992 using DLR's ATTAS In-Flight Simulator. The flight test included runs with two different control laws: a conventional control scheme and the alternate control scheme (ACS). Results of the experiment demonstrated both the negative effect of rate saturation and the effectiveness of ACS to reduce the equivalent time delay and improve tracking performance. In order to further validate the concept of an alternate control scheme, the algorithms were adapted for use with a model-following control system. Pilot-in-the-loop simulations have shown improved performance through the use of ACS during rate saturated conditions. A second flight test will be performed this year in order to further evaluate the use of the alternate control scheme to eliminate the rate limit induced time delay and reduce the danger of PIO.

SAAB EXPERIENCE WITH PIO

Kullberg, E., Saab-Scania, Sweden; Elgerona, Per-Olov, Saab-Scania, Sweden; Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations; Feb 1, 1995, 9 p; In English; See also 19950024640; Copyright; Avail: CASI; A02, Hardcopy; A02, Microfiche

The past experience in Sweden with PIO is reviewed, which has been so publicly witnessed with the second accident to the JAS-39 aircraft at the Stockholm Water Festival. Prior to commencing on the JAS-39 project, SAAB's experience of the PIO phenomenon had commenced with the J-35 aircraft. This aircraft had high stick sensitivity combined with a linear gearing of the stick to elevator. Following the PIO, the solution devised was to add a nonlinear gearing and

improve the stability augmentation of the system. For the next aircraft project, the AJ-37 Viggen, significant work was performed on the handling qualities and resistance to PIO, based upon new information received during the 1960's from Ashkenas, McRuer, and A'Harrach. By 1963, Sweden had developed its own specification for flight control system design and for handling qualities. The latest versions of this AJ-37 aircraft have a digital flight control system. The AJ-37 Viggen has never experienced a problem with PIO in its service to date. The JAS-39 flight control system originated from demonstration work performed by SAAB on a FBW AJ-37 Viggen aircraft. This aircraft had been flown with instability levels of up to 4 percent chord at low Mach Number. This was the limit for this aircraft. Although this aircraft was reported to have experienced Level 2 or 3 handling, due to excessive time delays within the flight control system, it never experienced rate limiting or PIO. On this basis, it was deemed that there was sufficient knowledge and confidence to proceed with the JAS-39 aircraft project, and the JAS-39 specification was written around this experience, with a demanding handling qualities requirement.

AEROELASTIC PILOT-IN-THE-LOOP OSCILLATIONS

Norton, W. J., Department of the Air Force, USA; Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations; Feb 1, 1995, 14 p; In English; See also 19950024640; Copyright; Avail: CASI; A03, Hardcopy; A02, Microfiche

Pilot-induced oscillation (PIO) is an unwanted and inadvertent closed-loop coupling between the pilot and one or more independent response variables of an aircraft. PIO typically results when the pilot attempts to perform a high gain tracking task using the usual cues of acceleration or attitude. Control system and aircraft characteristics within the bandwidth in which the pilot is active can contribute to a coupling between the pilot response and aircraft dynamics. The result is a neutrally damped or undamped out-of-control condition in which the pilot is often making intentional extreme and repetitive inputs in an effort to damp the motion but only serves to enhance it. Pilot-augmented oscillation (PAO) is an unintentional closed-loop coupling which does not involve a tracking task. Another aircraft variable which may lead to PIO or PAO is aeroelastic deformation of the vehicle structure. This elastic response can produce pilot cues or aircraft rigid body motion which can be enhanced when the pilot attempts to damp the oscillation and PIO results. Or, the elastic oscillations alone may lead to PAO. The potential for aeroelastic pilot-in-the-loop coupling is not widely recognized, and this can mean resources expended in ineffectual or nonoptimal solutions to the problem until the aeroelastic source is recognized. This paper will characterize the aeroelastic/pilot coupling phenomena without reproducing the fundamental research which has already been published on more general PIO. Examples of aeroelastic PIO and PAO will be provided to illustrate the various ways in which the phenomena can manifest itself, including recent experiences with the C-17A and the V-22. An examination of the potential for predicting this coupling will also be provided. Lastly, recommendations for flight test methodology to uncover and investigate aeroelastic pilot-in-the-loop coupling will be provided.

CALSPAN EXPERIENCE OF PIO AND THE EFFECTS OF RATE LIMITING

Chalk, Charles R., Chalk (Charles R.), USA; Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations; Feb 1, 1995, 12 p; In English; See also 19950024640; Copyright; Avail: CASI; A03, Hardcopy; A02, Microfiche

The experience of PIO within the Calspan Corporation is considerable, following a long standing interest in the subject. During this experience, the major concern that has been uncovered is that of the attitude towards the pilot following a PIO incident. There is still a tendency in many areas of aviation to consider a PIO as a failure of the

pilot, whereas it must be properly regarded as a failure of the control system and its design process. Over a period of some years, the Calspan Corporation has undertaken a series of experiments with the NT-33A and Lear Jet aircraft to examine the effects of rate limiting compensating devices. The notes which follow summarize the presentation given on some of the aspects which have been investigated both analytically and experimentally in flight tests.

Tactical rotary wing and low-level, fixed wing aircraft operating in high threat areas require improvements in night and adverse weather conditions in order to increase survivability, improve operational performance, and reduce pilot workload. Recent developments and the results of on-going programs suggest that increased automation and optimized integration of sensors, guidance/navigation, control and display systems, and weapons provide approaches to greatly enhanced capability in night operation. The purpose of this symposium is to support the evolutions and envelopment of alternative core structures which will lead to the fielding of effective low-level and N.O.E. night operations systems for fixed and rotary wing aircraft.

The ability to carry out night strikes is sought by all countries. Limited to current budgetary constraints and performance of optoelectronic sensors, nacelle mounted active infrared night vision binoculars are the answer to this need. From the simplest to the most complex systems, these can be developed at reasonable costs for in-service aircraft.

AN APPROACH TO SENSOR DATA FUSION FOR FLYING AND LANDING AID PURPOSE

Balzarotti, G., Fabbrica Italiana Apparecchiature Radioelettriche S.p.A., Italy; Fiori, L., Fabbrica Italiana Apparecchiature Radioelettriche S.p.A., Italy; Midollini, B., Fabbrica Italiana Apparecchiature Radioelettriche S.p.A., Italy; Vigliani, G., Fabbrica Italiana Apparecchiature Radioelettriche S.p.A., Italy; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 8 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Modern aircraft, operating in hostile environments, at night and in adverse weather conditions, are usually equipped with a number of sensors, both active and passive, which separately provide the pilot with data and images and represent a substantial aid during the mission. Novel techniques are currently under development to further improve the effectiveness of the mission by integrating and interpreting the produced data before making them available to the pilot. This paper analyzes the data fusion following a growing integration level criteria. The levels in the integration flow where the fusion is effectively applicable are investigated starting from raw signal (lowest level) up to processed data from sensors, even located on different sites

(highest level). Schematically the integration levels considered in the paper will be the following: (1) sensor/pre-processing; (2) processing; (3) display; (4) operative modes; and (5) multiple platforms.

19950026078 Eltro G.m.b.H., Heidelberg, Germany
LASER BASED OBSTACLE WARNING SENSORS FOR HELICOPTERS

Buechtemann, W., Eltro G.m.b.H., Germany; Eibert, M., Dornier Luftfahrt G.m.b.H., Germany; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 8 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Helicopters and aircraft in low-level flight have a high risk to strike obstacles, in particular power lines and overhead wires down to the size of telephone wires. This risk increases when flying nap-of-the-earth (N.O.E.), at night and under poor visibility conditions. Existing night vision equipment cannot provide safe detection of these dangerous obstacles. For these reasons there has been, for quite some time, a widely accepted need for reliable means of detecting obstacles, particularly under all acceptable Low-Level and N.O.E. flying conditions. Solutions to this problem, proposed and developed in the past, have been mainly based on millimeter wave technology. More recently, laser based system are being developed which offer good capabilities to solve this task without many of the shortcomings of the radar systems. The laser radar solution, on the other hand, has to prove its adequacy under limited visibility conditions. This paper presents laser radar developments in the thermal infrared (10 micron region) and near infrared spectral regions for helicopter obstacle warning systems. Both Dornier and Eltro have designed, built and demonstrated laser radar sensors for obstacle warning. Eltro has designed and built an experimental laser radar based on CO₂-lasers and heterodyne detection. Ranges in excess of 600 m against railway overhead wires and 1100 m against extended targets have been achieved. Dornier has designed, built and flight demonstrated a GaAs laser obstacle warning sensor operating at 0.9 micron. Merits and limitations of these technologies are being discussed.

DEVELOPMENT AND FLIGHT TESTING OF AN OBSTACLE AVOIDANCE SYSTEM FOR US ARMY HELICOPTERS

Holder, Sandra L., Army Night Vision Lab., USA; Branigan, Robert G., Army Night Vision Lab., USA; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 10 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Today's Army Aviator must fly both low and fast in order to survive against modern anti-aircraft weapons. Such flight brings him perilously close to wires, poles, trees and other obstacles. Helicopter collisions with such obstacles have been a long-standing concern for the USA Army. In order to address this issue, the Night Vision and Electronic Sensors Directorate (NVESD) has sponsored the development of an Obstacle Avoidance System (OASYS) capable of being integrated onto an aircraft and operated in real time. Under this program, two different systems have been fabricated and delivered. Both systems utilize direct detection laser radar sensors which operate in the eyesafe regime. The two systems differ primarily in the type of laser source used. The first system, developed by Northrop Corporation, utilizes a diode laser operating at 850 nm with an average repetition rate of 64 kHz. The second system, developed by Fibertek Inc., utilizes a diode-pumped solid-state laser operating at 1.54 microns with a repetition rate of 15 kHz. Both systems have been integrated onto helicopters and extensive flight evaluations have been completed. A number of important lessons have been learned regarding the individual technologies involved and obstacle avoidance as a whole. Both systems have been demonstrated to enhance mission effectiveness and flight safety. Furthermore, the technologies have been shown to

be mature enough to justify proceeding to an Engineering and Manufacturing Development (EMD) phase in which issues relating to cost, volume and weight are addressed.

RAF aircraft accidents in the last 2 years have included a Hercules in Scotland, where all 9 on board were killed, 2 Harriers, one on operations over Iraq and one on a training flight in England, and a Tornado F-3 and its crew off Cyprus. The RAF also suffered 2 mid-air collision accidents, one involving a Tornado GR-1 and a civilian helicopter and the other 2 Tornados in formation over Canada. Human factors and the maintenance of situational awareness were a feature in all these accidents. This paper attempts to identify some of the human factors linking these accidents.

Aircraft disinsection is an important tool in preventing the introduction of unwanted pests into a country when an aircraft is returning to its home base. To prevent risks to air crew health, aircraft safety, and industry, Canada's Department of National Defence (DND) has reviewed the importance of aircraft disinsection and the potential problems associated with execution. Over the past two decades, various directives for air crew maintenance personnel, and preventive medicine technicians have been developed and updated periodically. This aircraft disinsection review is part of the latest effort to revise DND's administrative orders on aircraft disinsection. Existing Canadian and foreign legislation, regulations, and recommendations dealing with aircraft disinsection were reviewed. This review also summarises the information that was gathered from various officials involved in the regulation of introduced pests, pesticide registration, and safe pesticide use. Aircraft disinsection technology has evolved over the years since its inception. Practical, up-to-date information on current technologies was gathered, through numerous meetings and correspondence, from researchers, private companies involved in aircraft disinsection, air force personnel, and representatives of civilian air carriers who are active worldwide. The end-result was the development of a current, standard operating procedure for disinsection of Canadian Air Force aircraft in the form of an Air Command Administrative Order. It may serve as a model for the Air Forces and air carriers of other NATO countries.

AIR TRAFFIC CONTROL PROCEDURES FOR THE AVOIDANCE OF WAKE VORTEX ENCOUNTERS: TODAY AND FUTURE DEVELOPMENTS BY DEUTSCHE FLUGSICHERUNG GMBH

Brenner, Frank, Deutsche Flugsicherung G.m.b.H., Germany; The Characterisation and Modification of Wakes from Lifting Vehicles in Fluids; Nov. 1996; 14p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

An increasing number of movements of flights leads to the necessity to space aircraft more and more often with the minimum values in order to avoid delays in air traffic. The question is: What are the minimum values? Are the minima established a long time ago by ICAO still valid? On the one hand trials have shown that these values need not necessarily to be obtained if special conditions prevail and the pilot of a succeeding aircraft is able and willing to adjust his flight path in such a way that the safety of the aircraft is not endangered by wake vortices produced by the preceding aircraft. This means the pilots and the air traffic controllers need to understand the behavior of wake vortices and closely cooperate in achieving a high throughput of traffic whilst minimizing the risk of wake vortices encounters.

The wake issue has widespread concern to commercial aviation because of its hazardous effects on flight safety, and as a limiting factor to increase airport capacity and aircraft efficiency. Results reveal the structure of a near field wake to be of complex nature, even though only the steady-state sector of flow was accessible with available testing gear. Flowfield evaluation focused on: vortex relative motion; streamwise vortex development; crossflow velocity structure; streamwise velocity structure; total pressure loss; and streamwise vorticity redistribution.

Wake vortex separation standards are used to limit the frequency and severity of wake vortex encounters under instrument flight rules (IFR). One of the goals of wake vortex research is to develop models that can specify the safe separation for any aircraft pair and hence can be used to judge the safety of proposed changes in separation standards. A direct approach to defining a safe separation model is presented in this paper. The observed UK vortex encounter rates are fitted to a model that defines equal-encounter-rate (EER) separations as a function of the parameters of the leading and following aircraft (specifically their wingspans). Safety is specified by defining the acceptable encounter rate. The first analysis fits the EER separation to powers of the wingspans of the leading and following aircraft. When these powers (1.13 and -0.95, respectively) are found to be close to one, the analysis is repeated using the leader-follower span ratio.

The safe separation of a store from any aircraft represents potentially the most hazardous phase of the store release process. The paper examines in turn the various mechanical and aerodynamic influences that come into play during store separation, reviews the requirements imposed by national standards, and explores how modeling and instrumentation techniques have advanced to benefit programs that include verification of safe store separation.

AUDIO WARNINGS FOR MILITARY AIRCRAFT

James, S. H., Defence Research Agency, UK; Jun. 1997; 20p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A survey of warning systems currently installed in military aircraft showed that generally they are of poor design. Simply constructed warning sounds have been added to aircraft as and when deemed necessary and hence, have been installed on an individual basis rather than as an integrated warning set. As more and more of these types of sounds are introduced discrimination will become more difficult and confusions increase. Additionally, the warnings are continuous in nature and presented at too high a volume which not only causes startle but interferes with communications, resulting in aircrew seeking the audio mute rather than dealing with the problem at hand. Consequently, the audio warnings currently in use may prove counter-productive and have flight safety implications. This paper details the research conducted by DRA aimed at providing the UK military aircraft fleet with a standardised, fully integrated audio warning suite. To date the work has culminated in the development of a set of design guidelines and a presentation strategy that not only minimizes the number of warning sounds required in a warning set but that remains flexible to allow new warnings to be added without necessarily increasing the number of sounds required. The characteristics for trend indicating sounds are also defined and a protocol for their design detailed. Additionally, in an attempt to enhance the number of audio alerts aircrew can process, manage and respond to accurately, the feasibility of mapping aircraft threat related warnings in three dimensional space is discussed and future research areas detailed.

EXTENDING THE FREQUENCY RANGE OF EXISTING AUDITORY WARNINGS

Patterson, R. D., MRC Applied Psychology Unit, UK; Datta, A. J., MRC Applied Psychology Unit, UK; Jun. 1997; 8p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper discusses two projects involving auditory warnings in military helicopters and fixed-wing aircraft. The first project reports methods to increase the frequency range of the existing DRA auditory warnings without changing their sound quality. The need to extend the frequency range arose from the requirement for 'out-of-head' localization of warning sounds. In the second project, the purpose was to develop a new class of sounds to be used as threat warnings. The aim was to make threat warnings that had a distinct sound quality as a set but which were, at the same time, separately identifiable.

The Propulsion and Energetics Panel Symposium on Aircraft Fire Safety was held in Dresden, Germany from 14-17 October 1996. It dealt with military and civil aspects of fire safety, covering combat-induced damage and technical sources of fire, fire prevention, fire fighting, fire damage control, and fire damage to humans and equipment. Environmental issues including Halon replacement were addressed. There were 7 sessions (37 papers) and a keynote address: Aircraft Fire Safety; Fires and Fire Handling; On-board Fire

Extinguishing Systems; Certification and Testing; Materials and Structure Design for Fire Safety; Aeromedical Aspects Including Smoke Toxicity; and Passenger Protection and Behaviour.

FIRE SAFETY AND FIRE PROTECTION FOR MILITARY TRANSPORT AIRCRAFT AS ADDRESSED IN A RECENT NATO/AGARD SURVIVABILITY STUDY

Schwartz, Eric R., McDonnell-Douglas Corp., USA; Park, Shawn, McDonnell-Douglas Corp., USA; Aircraft Fire Safety; Sep. 1997; 12p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper presents the major findings and conclusions related to fire safety and fire protection for military transport aircraft as determined by a recent NATO AGARD study. This study, entitled Enhancing the Survivability of Military Transport Aircraft, addressed all aspects of aircraft design for survivability including both susceptibility and vulnerability reduction techniques. However, in this paper we will focus only on those findings which relate to fire safety and protection. The AGARD study looked at the survivability of military transport aircraft during humanitarian and peacekeeping operations, such as encountered in Panama, Somalia, and the former Yugoslavian states. Typically, transport aircraft are not designed to fly into hostile areas and thus have little protection against ground and air threats. However, with changing political policies and military doctrine, NATO countries have been increasing the utilization of military transports in these potentially hostile roles. The AGARD study focused mainly on potential survivability enhancement retrofits for the current NATO tactical airlifters, the C-130, C-160, and G-222. However, survivability design features were also considered for potential new military transport aircraft such as the European Future Large Aircraft (FLA) and the conceptual USA (U.S.) Advanced Tactical Transport (ATT). This study considered both aircraft susceptibility (inability to avoid being hit by a threat) as well as aircraft vulnerability (inability to avoid damage if hit). The main threats that were considered included; small arms (7.62 mm), high caliber projectiles (12.7 and 23 mm) and hand-held infrared missiles. Larger threats were also considered, but transport survivability against these were mainly dependent on avoidance and susceptibility reduction. Against the smaller threats, several vulnerability shortfalls in the area of fire protection were noted for the C-130, C-160, and G222. The main shortfalls related to fire included; in-tank fire/explosion, void space fire/explosion, exterior fire, and hydraulic fluid fire. Engine fire was not considered a survivability problem since all aircraft in the study had adequate engine fire detection and suppression systems. Many potential solutions were considered to reduce the risk of fire and explosion in order to enhance aircraft survivability. Both passive and active solutions were reviewed, including those used with other military aircraft, and the latest technology being used on the U.S. C-17 and V-22 transport aircraft. Solutions considered included; self-sealing fuel tanks and fuel lines, fuel tank ullage inerting, fuel tank foam (rigid open cell type), dry bay foam (closed cell type), and fire extinguishing systems. The potential solutions were evaluated for ease of retrofit, applicability for new designs, operational restrictions, support requirements, weight, and cost. The major recommendations for retrofit on current aircraft included; fuel tank and dry bay foam, as well as fire extinguishing systems. The major recommendations for consideration in new designs included; fuel tank and fuel line designs to minimize vulnerable areas, self-sealing fuel tanks and fuel lines, fuel tank ullage inerting using onboard inert gas generation (OBIGGS), dry bay inerting, and fire extinguishing systems.

A REVIEW OF FIRE RELATED ACCIDENTS, 1985-1995

Taylor, A. Frank, Cranfield Univ., UK; Sep. 1997; 8p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

In the 1975 and 1989 AGARD Symposia statistics were presented concerning the survival aspects of transport aircraft accidents. Although much relevant data was still missing it was concluded that not much had changed in the intervening years. Following the Manchester B737 fire accident in 1985 many important recommendations were made and much research has been completed. The current study reviews relevant accidents 'post-Manchester' and tries to assess to what extent the changes that have been made have improved our chances of escaping safely from an aircraft that is on fire or has been damaged sufficiently for fuel to have been spilt. As far as possible criteria identical to those used previously will be employed in order to make the comparisons valid, however it must be appreciated that international aviation is changing and any effects of these changes that can be quantified will also be discussed.

A REVIEW OF RECENT CIVIL AIR TRANSPORT ACCIDENTS/ INCIDENTS AND THEIR FIRE SAFETY IMPLICATIONS

Hill, Richard G., Federal Aviation Administration, USA; Blake, David R., Federal Aviation Administration, USA; Sep. 1997; 6p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper presents a brief summary of recent civil air transport accidents and major incidents involving fire. It updates the paper "Investigation and Characteristics of Major Fire Related Accidents in Civil Air Transports Over the Past Ten Years". A more detailed review of selected accidents/incidents is presented including their link to safety improvements made to-date in fire resistant materials and their impact on improved passenger survivability and the need for improvements in aircraft systems, such as oxygen, hydraulic and electrical, to further improve survivability. Research and Development to reduce aircraft fire fatalities is discussed and justified using accident/incident data. The paper discusses the problem of Halon replacement. Accident/incident data is used to show the need to choose replacement agents that can perform well against real aircraft fires. The need for realistic test methods is discussed. The paper concludes that additional improvements in passenger fire survivability are needed and attainable.

A COMPUTER-BASED SIMULATION AND RISK ASSESSMENT MODEL FOR INVESTIGATION OF AIRLINER FIRE SAFETY

Macey, P., Cranfield Univ., UK; Cordey-Hayes, M., Cranfield Univ., UK; Taylor, A. F., Cranfield Univ., UK; Phillips, W. G. B., Cranfield Univ., UK; Sep. 1997; 12p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A computer simulation model has been developed to investigate fire safety issues in commercial passenger aircraft operations. The aim of the work has been to create a computer-based analysis tool that generates representative aircraft accident scenarios and then simulates their outcome in terms of passenger injuries and fatalities. The details of the accident scenarios are formulated to closely match the type of events that are known to have occurred in aircraft accidents over the last 40 years. This information has been obtained by compiling a database and undertaking detailed analysis of approximately 200 airliner fire accidents. In addition to utilizing historical data, the modeling work has incorporated many of the key findings obtained from experimental research undertaken by the world's air safety community. The unique feature of the simulation process is that all critical aspects of the accident scenario have been analyzed and catered for in the formative stages of the program development. This has enabled complex effects, such as cabin crash disruption, impact trauma injuries, fire spread, smoke incapacitation and passenger evacuation to be simulated in a balanced and integrated manner. The work is intended to further the general appreciation and understanding of the complex events that lead to fatalities in aircraft fire accidents. This is achieved by analyzing all contributory factors that are likely to

03 AIR TRANSPORTATION AND SAFETY

arise in real fire accident scenarios and undertaking quantitative risk assessment through the use of novel simulation methods. Future developments will enable the undertaking of a systematic exploration and appraisal of the effectiveness of both current and future aircraft fire safety policies.

NUMERICAL SIMULATIONS OF AIRCRAFT CABIN FIRE SUPPRESSION

Hadjisophocleous, George, National Research Council of Canada, Canada; Cao, Shu, National Research Council of Canada, Canada; Sep. 1997; 12p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper deals with the modeling, using Computational Fluid Dynamics (CFD) models, of the suppression of aircraft cabin fires using a waterspray system. Combustion was computed using a multi-reaction combustion model and the waterspray trajectories were calculated using a transient Lagrangian model. A fire with a heat release rate of 50 kW was simulated using a pan containing heptane and used to determine the suppression effectiveness of a fine waterspray system. The watersprays were generated using a single nozzle located near the ceiling of the cabin right above the pan. The results showed that, with adequate water mass flow rate, the waterspray system was able to extinguish the assumed fire. With lower mass flow rates, the fire was not extinguished, however, the watersprays were able to cool the hot gases and to maintain survivable conditions in the cabin in terms of temperature. It is important to note, however, that the modeled fire had a fixed area and fire spread was not considered. Allowing the fire to spread to a larger area may result in different extinguishment characteristics. This paper demonstrates that it is possible to use CFD models to simulate the effectiveness of waterspray systems in suppressing aircraft cabin fires. Such models are useful tools to complement real tests and can be used to evaluate the impact of the various parameters on suppression effectiveness and cabin conditions.

Computer based mathematical models describing aircraft fire have a role to play in the design and development of safer aircraft, in the implementation of safer and more rigorous certification criteria and in post mortem accident investigation. As the cost involved in performing large-scale fire experiments for the next generation 'Ultra High Capacity Aircraft' (UHCA) are expected to be prohibitively high, the development and use of these modeling tools may become essential if these aircraft are to prove a safe and viable reality. By describing the present capabilities and limitations of aircraft fire models, this paper will examine the future development of these models in the areas of large scale applications through parallel computing, combustion modeling and extinguishment modeling.

POST-CRASH FIRE HAZARDS RESEARCH

Greene, Graham, Civil Aviation Authority, UK; Sep. 1997; 4p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A01, Hardcopy; A03, Microfiche

This paper outlines research funded by the Civil Aviation Authority (CAA) in the UK to explore potential health hazards at aircraft accident sites in the immediate post-crash situation i.e. after rescue and fire fighting has taken place. An initial study considered general hazards, which was followed by work exploring specific problems of composite materials. The intention was to be able to give best advice to personnel who need to be at an accident site, primarily civil authorities, aerodrome staff and accident investigators. There was also expected to be useful information for fire fighters, although they tend to be generally well protected through the nature of their tasks and do receive regular training in the management of hazards. The potential environmental impact of an accident would also be better understood. Many of the hazards are materials with known characteristics although use (quantities and locations) on aircraft may not be readily determined. Composite materials have less understood post-fire hazards although work to date indicates that current CAA advised precautions are adequate, although further work remains before a definitive position may be established. Although the research was funded by CAA, considerable help and advice has been given by the Air Accident Investigation Branch and the Royal Air Force.

AIRCRAFT POST CRASH MANAGEMENT: THE ROYAL AIR FORCE APPROACH

Andrews, J. W. T., Royal Air Force, UK; Sep. 1997; 6p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The Royal Air Force has the responsibility for the recovery and transportation of crashed or disabled British military fixed wing aircraft - worldwide - and this responsibility is discharged by the Aircraft Recovery & Transportation Flight (AR&TF) at RAF St Athan in South Wales. The corresponding responsibility for the recovery of rotary-wing aircraft rests with the Royal Navy. Up to the end of 1990, "the nearest flying unit" had a major responsibility for dealing with aircraft crash recovery and we had no specific concerns about health hazards at aircraft crash sites, however, the crash of a Harrier GR5 in October 1990 completely altered our perceptions and approach to what is now almost universally referred to as Post Crash Management (PCM).

FIRE SAFETY CONCEPT FOR A MODERN COMBAT AIRCRAFT

Manthey, Christian, Kidde-Deugra, Germany; Sep. 1997; 6p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Engine auxiliary power unit fire detection and extinguishing systems are now standard equipment on modern aircraft and have been installed for many years. The majority of these utilize continuous thermal detection systems which will respond to changes in temperature within the protected compartment. More recently the latest generation combat aircraft have used optical detection systems in place of these traditional thermal detection methods. This offers weight saving and much faster response to fire. Protection of other areas, such as fuel tanks and dry bays, is fast becoming essential as the combat threat from even small arms projectiles increase. It is fundamental to the operational role of combat aircraft that they are exposed to high levels of risk, particularly that resulting from hostile action. A wide range of countermeasures can be, and are, taken to minimize the probability of an aggressor succeeding in damaging the aircraft, but these measures cannot be totally successful and the consequences of sustaining damage must be considered. Studies have been carried out to determine which areas of the aircraft are most susceptible to combat threats and which areas or systems are most likely to cause aircraft damage or loss from fire and explosion if combat damage was sustained. The fuselage, tail and wing were not surprisingly, the areas which suffered the most combat hits contributing to more than 70% of

incidents. Fuel and hydraulic systems were involved in almost 80% of combat losses in fighter aircraft and similar figures were reported for transport aircraft.

WATER SPRAY SYSTEM DEVELOPMENT AND EVALUATION FOR ENHANCED POSTCRASH FIRE SURVIVABILITY AND IN-FLIGHT PROTECTION IN CARGO COMPARTMENTS

Marker, Timothy R., Federal Aviation Administration, USA; Sarkos, Constantine P., Federal Aviation Administration, USA; Hill, Richard G., Federal Aviation Administration, USA; Sep. 1997; 12p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper describes full-scale fire tests conducted by the Federal Aviation Administration (FAA) to evaluate and optimize water spray systems in two specific aircraft fire safety applications. The first application was an onboard cabin water spray system designed to improve postcrash fire survivability. The goal is to suppress a severe cabin fire, initiated by a large external fuel fire, in order to improve the available time for passenger evacuation. The second application was a cargo compartment water spray system for the purpose of suppressing and controlling in-flight cargo/luggage fires. In this case, the water spray system must suppress and contain a worst-case, deep-seated fire for as long as 180 minutes, or until an airplane can be safely landed.

SYNTHESIS AND PROPERTIES OF VARIOUS ALTERNATIVE FIRE EXTINGUISHING AGENTS

Rudolph, W., Solvay Fluor und Derivate G.m.b.H., Germany; Rieland, M., Solvay Fluor und Derivate G.m.b.H., Germany; Sep. 1997; 6p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The two bromine based fire extinguishing agents, HALON 1211 (CF₂ClBr) and HALON 1301 (CF₃Br), are extremely effective at extinguishing major conflagrations. Particularly they offer a reliable way of combating fuel, solvent and gas fires. However, these agents are also characterized by a high Ozone Depletion Potential (ODP) and this is the reason why their production has been almost entirely phased out in those countries that have ratified the Montreal Protocol. The paper discusses the synthesis and properties of various alternative fire extinguishing agents and choose best candidates as an alternative for the old HALONS.

EXTINGUISHING OF AIRCRAFT INTERIOR FIRES WITH HALON REPLACEMENTS FOR HANDHELD EXTINGUISHERS

Kallergis, K. M., Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Germany; Sep. 1997; 10p; In English; See also 19970034906; Original contains color illustration; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Because the halons have to be abandoned in the near future the effectiveness of possible replacements for attacking initial fires in civil aircrafts must be investigated. This lecture reports on fire extinguishing experiments with handheld extinguishers on aircraft carpet and seats. Three so-called halon alternatives were compared to the Halon 1211, which is still in use in aviation. To set the aircraft interior on fire for experimental purposes, gasoline was used as fire accelerator which is thought to be realistic in a terroristic attack versus an

aircraft. Furthermore, a small-scale hidden fire mock-up is presented. Employing this mock-up the extinguishing qualities of new extinguishing agents can be estimated by laboratory means.

HALON REPLACEMENT: AVIATION TEST CRITERIA

Povey, Nick J., Civil Aviation Authority, UK; Sep. 1997; 10p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Halon is widely used in civil aircraft. In a typical wide body jet aircraft passengers will be protected by both Halon 1301 and Halon 1211. Over the past 30 years, because of its exceptional fire fighting performance, relative low cost, ready availability and low weight and volume to effectiveness, Halon 1301 has evolved as the agent of choice. A vast amount of testing has been done during that period to certificate Halon fire suppression systems in engine nacelles, auxiliary power unit compartments, trash containers, and cargo compartments of various size and shape. In addition, Halon 1211 in hand held extinguishers has been found to be very effective in fighting the most hazardous of in-flight fires. This paper discusses the minimum performance criteria for replacement hand held portable extinguishers for aircraft cabin fire protection.

19970034920 Federal Aviation Administration, Fire Safety Sect., Atlantic City, NJ United States

DESCRIPTION AND STATUS OF CIVIL AVIATION'S HALON REPLACEMENT PROGRAM

Hill, Richard G., Federal Aviation Administration, USA; Sarkos, Constantine P., Federal Aviation Administration, USA; Sep. 1997; 6p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Civil aviation has a major program to replace halons with environmentally acceptable agents/systems in transport aircraft fire extinguishing systems. The program is international in participation and is harmonized amongst the regulatory authorities in the U.S., Europe and Canada. An International Halon Replacement Working Group provides for frequent review and critique of progress, task group studies of issues that arise and planning of technical test activities. The program emphasizes full-scale fire tests to evaluate the effectiveness of replacement/alternative agents and to develop certification criteria for those agents that are equivalent to halon in firefighting effectiveness and are compatible with operational requirements. This will ensure that the current level of fire safety will continue to be maintained in future aircraft fire extinguishing systems.

PERFORMANCE OF FIRE FIGHTING POWDERS

Brogan, E., Faverdale Technology Centre, UK; Sep. 1997; 6p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

A series of dry powder fire extinguishing tests have been carried out by Faverdale Technology Centre for the Civil Aviation Authority's Safety Regulation Group. The aim of the test programme was to design a test specific to those aviation fuel fires which are not covered by normal class 'B' fire testing. It would then be possible to assess objectively the performance of dry powders for aviation uses. A specially designed test rig on which the fire tests would be carried out was designed and developed to model a running fuel fire and spray fire. The test method involved the manual application of the dry powder by personnel trained in the art of firefighting. The test programme was split into three phases: Phase A - set out to determine the suitability of Monnex(R) dry powder as a benchmark for future tests by extinguishing fires of Jet A1 aviation fuel within a 0.66 sq m pool tray. Phase B - concentrated upon small scale testing on a 2.8 sq m pool tray, using Monnex(R) and a standard powder. Phase C - comprised of an inves-

03 AIR TRANSPORTATION AND SAFETY

tigation into the optimum mass of dry powder required to extinguish two different full scale fire test scenarios; that is a cascade fire and the spray fire. Three different types of dry powder were employed, one Monnex(R) and two standard powders. All the tests were instrumented with metal sheathed thermocouples and heat flux meters to monitor the fire characteristics of temperature and radiant and convective heat flux respectively. The fire test methods used are described and the performance of the dry powders are presented in this paper. The results from the Monnex(R) tests are compared with the results from the standard powder tests. Particular attention was paid to the mass of powder required to extinguish each test fire. Although two different standard powders were used, only one of these was particularly suited to class B fires, hence the performance of this other powder was seen to be totally ineffective against any of the fuel fires it was tested on. The other standard powder was suitable for class B fires and the average mass used to extinguish the spray and cascade fires was more than the average mass of Monnex(R) required for the same fires. In summary Monnex(R) used less powder to extinguish the Phase B and C fires and was therefore considered to be a suitable agent to be used as a benchmark for further tests. This work is not conclusive and current investigations are studying the effect of application discharge rate of Monnex(R). Once these studies show the optimum application rate of Monnex(R), work to compare with other dry powders will resume.

The demonstration of fire performance of reactor components and cockpits (of a airplane) often requires one to carry out tests in the presence of a flame generated by a burner. During the 1950s, standardization documents were established, and associated testing devices (burners) were the focus, mainly to verify the fire performance of fuel oil piping systems and operation of fire detection devices. More recently, the more frequently common use of these devices to demonstrate fire performance of quite different equipment and components installed on engines and cockpits of modern airplanes has demonstrated certain shortcomings pertaining to standards as well as existing burners. The goal of the publication is to reveal the work conducted by SNECMA, in association with official French departments (STPA) and the propulsion test center (CEPr) to improve exiting materials, to simplify their use, and especially to make them equivalent,

especially propane and fuel oil burners. The study also presents analysis devices which have been developed and used at Snecma in combination with the tests.

A combustor burn-through can give rise to an under-expanded, sonic or supersonic jet of gases and flames out of the combustor. The pressure and temperature in the jet may be as high as the highest values of pressure and temperature arising in the combustor. In order to protect the engine and aircraft components from exposure to the jet over a period of time, a fire shield is installed adjoining the combustor. The USA Federal Aviation Administration has issued an Advisory Circular 20-135 redefining the requirements on the fire protection shield, and the overall objective of the project was to establish the basis for a preliminary design of a test facility and testing procedure for such fire shield materials. The current study was devoted to the determination of the mechanical and thermal loads that arise on the shield due to the impact of hot, high pressure, high speed jets. The results obtained assist in the identification of some of the essential features required in a test facility, and the test plans and procedures.

19970034925 Daimler-Benz Aerospace A.G., Military Aircraft Div., Munich, Germany

STRUCTURAL DESIGN CONSIDERATIONS FOR AIRCRAFT FIRE SAFETY

Voglsinger, M., Daimler-Benz Aerospace A.G., Germany; Lang, R., Daimler-Benz Aerospace A.G., Germany; Guenther, G., Daimler-Benz Aerospace A.G., Germany; Woerdehoff, J., Daimler-Benz Aerospace A.G., Germany; Sep. 1997; 12p; In English; See also 19970034906; Original contains color illustration; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Fire cannot be completely prevented by design and material means, in particular those caused by armor piercing munitions. Structural aims are therefore: (1) to keep the fire within the fire zones, which are designed to withstand fire exposure for a certain time accepting strength degradation; (2) To protect the primary structure, essential for structural integrity. Protection can be provided by separation, sealing, insulation, ventilation (cooling); (3) To select heat resistant materials in these areas accepting mass penalties; to provide redundant load paths, accepting reduced strength capability; (3) to size critical structural elements for limited fire/heat exposure. In case of fire non-destructive and destructive methods to determine the residual strength have limited reliability due to the unknown temperature and time the structure has been exposed to. Temperature-gauge-plates in the fire zones could ease the problem.

BURNTHROUGH RESISTANCE OF FUSELAGE AND CABIN STRUCTURES

Marker, Timothy R., Federal Aviation Administration, USA; Dodd, Darren C., Faverdale Technology Centre, UK; Povey, Nick J., Civil Aviation Authority, UK; Sep. 1997; 14p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper describes the joint research project undertaken by the United States Federal Aviation Administration (FAA) and the UK Civil Aviation Authority (CAA) to evaluate and improve upon the fuselage burnthrough resistance of transport category aircraft to large fuel fire

exposure. In an earlier project several surplus transport aircraft were exposed to large area fuel fires. During these tests, the fire entry points, likely fire paths to the cabin, and time frame involved for this to occur were investigated. The current project is an extension of this earlier work. The project is divided into several phases: development of a full scale testing device, development of a medium scale testing device, and follow-on research leading to the potential development of specifications for materials, systems and components which would increase fuselage burnthrough resistance. The CAA tasked Faverdale Technology Centre (FTC) to develop a medium scale test apparatus. FTC completed construction of the testing apparatus in 1993. The FAA had the responsibility of developing a full-scale burnthrough test rig, which was completed in 1995, at the FAA Technical Center in Atlantic City. Several tests have been completed in the full scale test rig. The test results of both the medium and full-scale rigs will be discussed, along with future considerations. In Europe an Industrial consortium led by Airbus Industrie will be proposing an Industrial Materials and Technology research project to the European Commission. This project will build on the work initiated by the Authorities. The objective is to identify materials and processes capable of substantially improving burnthrough resistance and also capable of being introduced to aircraft production lines in a timely and economical manner.

TITANIUM FIRE IN JET ENGINES**

Uihlein, T., Motoren- und Turbinen-Union G.m.b.H., Germany; Schlegel, H., Motoren- und Turbinen-Union G.m.b.H., Germany; Sep. 1997; 12p; In English; See also 19970034906; Original contains color illustrations; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

In aero-engines, titanium fire occurs in the fan and compressor where titanium is indispensable because of its high strength-to-weight ratio. Titanium alloys are mainly used for blading, casings and disks. Consequently, if bearing- or blade-failure occurs, the possibility of an uncontained titanium fire cannot be excluded. A titanium fire is a very short event of about 4 to 20 seconds duration depending on the engine design and the operating conditions. It is a violent conflagration accompanied by temperatures as high as 3,300 C. This energy destroys surrounding materials, including steel and nickel alloys, by burning and melting. When this happens, the airframe structure can be severely damaged, even resulting in the loss of the aircraft. Extinguishing the fire is impossible because of its rapid propagation and the very short time between its detection after uncontainment and its termination. Common fire-extinguishing agents are not suitable for quenching a titanium fire because their composition is inadequate and sufficient quantity is not available. But these agents can prevent propagation of the fire in the engine bay. The risk involved can be avoided by such measures as intelligent design, fire-preventive coatings, and use of titanium alloys that are not easily combustible. The development of preventive measures calls for rig tests in order to simulate burning conditions, and to verify the efficacy of the measures. Titanium can then be used safely in advanced technology engines for modern aircraft.

GLARE(R): A STRUCTURAL MATERIAL FOR FIRE RESISTANT AIRCRAFT FUSELAGES**

Roebroeks, G. H. J. J., Structural Laminates Co., Netherlands; Sep. 1997; 14p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

GLARE(R) consists of thin aluminum alloy sheet and fiber layers containing strong unidirectional glass fibers and epoxy adhesive. The material has been optimized to overcome the corrosion and fatigue problems of monolithic aluminum alloys and meets all requirements for use in primary aircraft structures. In 1994 several GLARE grades with biaxial fiber layers were certified to the fire resistance requirements for cargo liners specified in FAR 25.855. The material even resists an

1100 C flame for more than 15 minutes without penetration. The fire resistance of GLARE together with the materials' outstanding impact properties makes GLARE an attractive candidate for future application in cargo liners and floors. The behavior of GLARE in blast-resistant containers providing fire resistance after the blast, proves the materials' capabilities. Due to its material properties GLARE is also attractive for fuselage skin applications. This is one of the few options to have fire resistant fuselages in the near future.

NEW FIRE SAFE MATERIAL FOR CABIN INTERIORS**

Lyon, Richard E., Federal Aviation Administration, USA; Sorathia, Usman, Naval Surface Warfare Center, USA; Balaguru, P. N., Rutgers - The State Univ., USA; Foden, Andrew, Rutgers - The State Univ., USA; Davidovits, Joseph, Geopolymer Inst., France; Davidovics, Michele, Geopolymer Inst., France; Sep. 1997; 8p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The fire response of a potassium aluminosilicate matrix (GEOPOLYMER) carbon fiber composite was measured and the results compared to organic matrix composites being used or considered for aircraft cabin interior applications. At irradiance levels of 50 kW/sq m typical of the heat flux in a well developed cabin fire, glass- or carbon-fiber reinforced polyester, vinylester, epoxy, bismaleimide, cyanate ester, polyimide, phenolic, and engineering thermoplastic laminates ignited readily and released appreciable heat and smoke, while carbon-fiber reinforced GEOPOLYMER composites did not ignite, burn, or release any smoke even after extended heat flux exposure. The GEOPOLYMER matrix carbon fiber composite retains sixty-three percent of its original flexural strength after a simulated large fire exposure.

TOXICITY OF COMBUSTION PRODUCTS IN MATERIALS USED FOR CABIN FIXTURES: A SIMPLIFIED METHOD OF EVALUATION
TOXICITE DES PRODUITS DE COMBUSTION DE MATERIAUX UTILISES DANS L'AMENAGEMENT CABINE: UNE METHODE D'EVALUATION SIMPLIFEE**

Mansuet, A., Centre d'Essais Aeronautique Toulouse, France; Petit, J.-F., Centre d'Essais Aeronautique Toulouse, France; Sep. 1997; 10p; In French; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

During the 73rd AGARD symposium held at SINTRA in 1989, we presented a methodology that combines an original fire model and an experimental protocol that allows one to evaluate the reaction of fire on the materials by physico-chemical criteria and also the toxicity of the combustion products by biological criteria as measured on monkeys. A method of classifying these materials has been proposed. Based on this methodology, the data gathered on 6 cabin fixture materials allow us to demonstrate a relation between the loss of mass, therefore the quantity of material degraded, and the incapacitation time of the animal.

Differentiating between competing possibilities is often a difficult task. When fire is involved the problems are so much greater because of the combustion of evidence and the capacity for mimicry. It is not unknown for finite answers to evade even the most cautious scrutiny and thus the answers to right and proper questions must, in medico-

03 AIR TRANSPORTATION AND SAFETY

legal language, be considered to be unascertained. In an aircraft accident, where much may depend upon the availability of precise information, this capacity for failure is troubling, as indeed it is in many other situations. However, because of the publicity which may accompany a fatal aircraft accident, with demands for changes in design, this is an impediment which causes great concern. Superficially it may seem that there ought not to be any difficulty, but this is to ignore the nature of fires. Moreover, it assumes that there are always clear indications of the cause and manner of death, and that the diagnostic difficulties are entirely a product of a failure to observe the signs. This is clearly not the case, though it has to be acknowledged that if the investigation is lacking, then there may not be enough evidence to make a proper diagnosis. This paper looks at these difficulties and places them in the context of the search for improved flight safety.

Many factors must be considered when using experimentally derived toxicity information to predict human response. Two important principles for appropriate use of toxicity data include obtaining information from an appropriate source and applying that information appropriately. Examples from our laboratory research are included, in which bench-scale combustion tests of advanced composite materials were conducted, collecting information such as mass loss rate, particle characteristics, and chemical characteristics of the smoke. Methods we employed in the evaluation of ACM combustion products include: (a) chemical analysis of the vapor and soot, (b) continuous plume temperature recording, (c) continuous monitoring of combustion gases, (d) determination of mass loss rate during combustion, and (e) morphologic evaluation of airborne particulate matter using light and electron microscopy, combined with computer-based image analysis.

ICE ACCRETION SIMULATION LA SIMULATION DE L'ACCUMULATION DE GLACE

Dec. 1997; 184p; In English

Report No.(s): AGARD-AR-344; ISBN 92-836-1067-9; Copyright Waived; Avail: CASI; A09, Hardcopy; A02, Microfiche

Ice Accretion Simulation is an important issue for flight safety. Every year several incidents happen which can be associated with severe icing problems. Although the bulk of them may be due to human mistakes during flight in icing conditions, some cases remain which are consequences of icing conditions never observed before or of failures not foreseen. Therefore, icing has always attracted great interest from aircraft manufacturers, authorities responsible for certification, and many researchers. The overall goal of the work presented in this report is to improve reliability, to reduce efforts and costs in civil and military aircraft certification/qualification procedures, and to improve civil and military aircraft flight safety. This report covers the effects of ice accretion on wings, tail surfaces, engine inlets, and rotary wings. Experimentally, besides the capability of icing wind tunnel facilities, the problems of spray tanker aircraft experiments are considered, the related similarity laws are examined, and the techniques for measuring droplet size and distribution are reviewed. The basic factors influencing computational predictions are discussed in detail, especially factors such as surface roughness and surface heat transfer. In addition to the 2D prediction methodology, the status of extensions to 3D is presented. An essential aim of a planned follow-on activity should be to establish some well-documented reference cases by suitable in-flight experiments, and to calibrate prediction tools and experimental facilities and techniques for those reference cases.

The overall goal of Working Group 23 was to improve the application of human factors analysis to operational enhancement and mishap prevention programs. Through different chapters, a variety of related topics were discussed in relation to the current status and approaches to aircraft accident/incident investigation, taking into account the human factors involved, procedures, categorization, tabulation and analysis. In addition, following a questionnaire which was widely distributed among all NATO countries, current data concerning the number of accidents, human factors studies, organizational aspects and the data collection were compiled and discussed. Also the possible approaches to conceptual models were described as a potential framework for the support and organisation of the principles and topics to be included in human factors/aeromedical data base. The Working Group reviewed current training programmes and discussed a common approach, in which human factors play a definite role. Examples of data bases currently in use are enclosed.

The audience today is primarily engineers, and the first objective is to convince them that flying a helicopter over water is more dangerous than flying a fixed wing aircraft over water. The evidence for this was first reported in 1984 by the UK Civil Aviation Authority (CAA) in the HARP Report (16). It concluded that the accident rate for helicopters operating over the North Sea was 2.0 per 100,000 flying hours compared to 0.4 for fixed wing aircraft. A subsequent review of accident data by the CAA (17) in 1995 reported that "In the 18 years from 1976 to 1993, the offshore industry has generated 2.2 million helicopter operating hours in the transportation of 38 million passenger for the loss of 85 lives in eight fatal accidents. This represented a fatality rate of 3.86 per 100,000 flying hours."

INJURY PREVENTION IN AIRCRAFT CRASHES: INVESTIGATIVE TECHNIQUES AND APPLICATIONS: GENERAL CONCEPTS AND OBJECTIVES

RiosTejada, Francisco, Centro de Instruccion de Medicina Aeroespacial, Spain; Injury Prevention in Aircraft Crashes: Investigative Techniques and Applications; Feb. 1998; 8p; In English; See also 19980048994; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

Accidents were investigated to reveal any of the wide range of human factors such as underlying illness, use of medications or drugs, fatigue, physical stresses, psychological and psychosocial stresses,

types and extension of injuries received, causes of impact injuries, emergency escape from the aircraft, smoke and fire as related to survivability, environmental conditions and a number of other biomedical conditions that may have contributed to the crash or be related to occupant injury or survival. A detailed analysis of injury sustained in aircraft impact would contribute to an understanding of the mechanisms involved and to know the design limitations of the human body to an impact and its survivability. While many similar injuries can be inflicted in a variety of ways, there are certain characteristic findings which suggest likely mechanisms of injury. For example, compression fractures of vertebral bodies in the low thoracic and lumbar spine typically occur as a consequence of forces acting approximately parallel to the long axis of the spine.

The report begins with a general discussion of existing tactical aircraft and a look into the necessary design characteristics of the next generation tactical airlifter. In section 2, the main elements in the development of the future European tactical air lifter are presented. These elements are comprised of: (1) the application of carbon reinforced plastics for the wing primary structure; (2) development of a turboprop engine for cruise speeds up to $M=0.72$; (3) aerodynamic design and propeller/wing integration; (4) application of a modern Electronic Flight Control System (EFCS); and (5) autonomous and silent high precision navigation and landing.

FLIGHT TEST OF A LOW-ALTITUDE HELICOPTER GUIDANCE SYSTEM WITH OBSTACLE AVOIDANCE CAPABILITY

Zelenka, Richard E., NASA Ames Research Center, USA; Clark, Raymond F., Army Command/Control and Systems Integration Directorate, USA; Branigan, Robert G., Army Night Vision Lab., USA; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 10 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Military aircraft regularly conduct missions that include low-altitude, near-terrain flight in order to increase covertness and payload effectiveness. Civilian applications include airborne fire fighting, police surveillance, search and rescue, and helicopter emergency medical service. Several fixed-wing aircraft now employ terrain elevation maps and forward-pointed radars to achieve automated terrain following or

terrain avoidance flight. Similar systems specialized to helicopters and their flight regime have not received as much attention. A helicopter guidance system relying on digitized terrain elevation maps has been developed that employs airborne navigation, mission requirements, aircraft performance limits, and radar altimeter returns to generate a valley-seeking, low-altitude trajectory between waypoints. The guidance trajectory is symbolically presented to the pilot on a helmet mounted display. This system has been flight tested to 150 ft (45.7 m) above ground level altitude at 80 kts, and is primarily limited by the ability of the pilot to perform manual detection and avoidance of unmapped hazards. In this study, a wide field of view laser radar sensor has been incorporated into this guidance system to assist the pilot in obstacle detection and avoidance, while expanding the system's operational flight envelope. The results from early flight tests of this system are presented. Low-altitude missions to 100 ft (30.5 m) altitude at 80n kts in the presence of unmapped natural and man-made obstacles were demonstrated while the pilot maintained situational awareness and tracking of the guidance trajectory. Further reductions in altitude are expected with continued flight testing.

Under the new conditions of defense production conversion and basing on high technologies that were developed for the production of military navigation technology the Central R&D Institute 'Elektropribor' has been developing and starts manufacturing products for civil application. Part of the project is dual usage technology. Three trends of the research are considered in this paper: (1) a gimbaled-type inertial system used to inspect railway tracks and in inertial geodesy; (2) gyro-stabilized gravity meter for geological prospecting of oil and gas from ships and planes; and (3) shipborne integrated chartgraphic navigation-controlling system.

EFFECTS OF THE SPECIFIC MILITARY ASPECTS OF SATELLITE NAVIGATION ON THE CIVIL USE OF GPS/GLONASS

Kayser, Dettlef, Technische Univ., Germany; Schaenzer, Gunther, Technische Univ., Germany; AGARD, Dual Usage in Military and Commercial Technology in Guidance and Control; Mar 1, 1995, 10 p; In English; See also 19950026705; Copyright; Avail: CASI; A02, Hardcopy; A02, Microfiche

Satellite Navigation is one of today's most promising and prospering infrastructure technologies. The performance improvement of this technology in comparison to the 'conventional' terrestrial navigation systems can be seen in almost every aspect, e.g.: (1) accuracy (decimeter level); (2) coverage (worldwide); (3) availability (24 hrs); (4) dimension (4 dimensional navigation (space and time)); and (5) system capacity (unlimited number of users). This led to a widespread application of satellite navigation and an according fast growing figure of satellite navigation equipment in the civil market. Up to now however, the final breakthrough in a lot of commercial applications, like in the aviation industry and in the maritime business, has not been reached. Beside some still unsolved technical aspects, like the integrity problem, the fact that GPS and GLONASS are military systems is one of the main hurdles. This institutional aspect, however, is not only an obstacle from the political point of view, but the military background of GPS/GLONASS led to lot of design features of the system, that have

a strong influence on the use of the system in civil applications. This paper will describe details on the different areas in which the military design limits the use of the system.

THE DLR RESEARCH PROGRAMME ON AN INTEGRATED MULTI SENSOR SYSTEM FOR SURFACE MOVEMENT GUIDANCE AND CONTROL

Klein, Kurt, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Dual Usage in Military and Commercial Technology in Guidance and Control; Mar 1, 1995, 8 p; In English; See also 19950026705; Copyright; Avail: CASI; A02, Hardcopy; A02, Microfiche

Based on the long-term experience in the field of Navigation and Air Traffic Control the Institute of Flight Guidance within the German Aerospace Research Establishment (DLR) is conducting a major effort to develop new solutions, system components and procedures for an integrated Surface Movement Guidance and Control System (SMGCS). In addition to and derived from the work on operational procedures, planning tools and HMI in our institute we are focusing our work on an integrated sensor concept to meet the requirements. SMGCS is to be regarded as an integrated concept that has a clearly defined modular approach to meet the particular requirements of a specific aerodrome. After outlining the conception several years ago a solution for the realization was evaluated in close co-operation with the DFS and the national industry. The objective of DLR research is: (1) to analyze the characteristics and to optimize as far as necessary the sensor candidates (e.g. DGPS, SSR Mode S Multilateration); (2) to evaluate the sensor information integration including data fusion algorithms; (3) to find solutions for the specific SMGCS data exchange problems via RF link; (4) to optimize the whole system loop in order to avoid interference by implementing modules into the system; and (5) to solve airfield operating problems by finding new functions within the SMGCS sensor domain. Although the main goal is the improvement of civil airport traffic, the work meets as well military operation problems. In addition, a lot of knowledge gained in military applications has to be considered. The research activities are funded by the DLR itself, to extend the theoretical and laboratory work to more realistic analysis an Experimental SMGCS is build up at the Braunschweig airport. This ESMGCS has the advantage of being very flexible with respect to the implementation of various subsystems and to tests in a real environment. Braunschweig airport is very suitable for experiments like this due to low traffic density and the available research infrastructure. Part of the ESMGCS will be a test environment that is based on the experiences gained during the MLS competition as well as during the development of the Avionics Flight Test System. Main part of the test environment is a measurement system for computing a reference situation assessment. The backbone of the ESMGCS is a high speed data network on fiber cable basis that connects the peripheral stations around the airfield to the master station. Different sensor subsystems or parts of these will be installed in the peripheral stations. The data fusion and the situation analysis are software processes within the master station. The derived situation information can be handed over to planning tools and to the tower simulator available in the DLR Institute of Flight Guidance.

LOW-LEVEL DATA FUSION FOR LANDING RUNWAYS DETECTION

Sliwa, Laure, Centre d'Etudes et de Recherches, France; Briottet, Xavier, Centre d'Etudes et de Recherches, France; AGARD, Dual Usage in Military and Commercial Technology in Guidance and Control; Mar 1, 1995, 11 p; In English; See also 19950026705; Copyright; Avail: CASI; A03, Hardcopy; A02, Microfiche

Data fusion brings reliability and robustness to both military and commercial systems. Data fusion allows in fact to fully apprehend a situation by using multisensors data redundancy and/or complementarity. The presented piece of work particularly concerns fusion of redundant data just outcoming from electro-optical sensors. The used methods are low-level fusion techniques, only preceded by a calibration step. These fusion techniques take into account the radiometric- and not geometric-data content. This paper is divided in two parts: the theoretical approach, and the guidance application of detecting a potential runway. The theoretical approach, according to the proposed goal, raises two problems. The one of suiting the multisensors' configuration to the mission. And the one of evaluating data at every step from ground reality to fusion. It appears necessary to define quality criteria to evaluate every sensor acquisition within the mission scope. The optimization of these criteria defines the weighted combination at the pixel level of the multispectral images. A priori knowledge of road materials spectral signatures and definition of appropriate quality criteria are necessary to detect roads or runways by pixel fusion. They allow to define the appropriate configuration of spectral bands to merge so that the runway shows up clearly. This paper presents the obtained results from low-level fusion of five broad bands (approximately 100 nm wide). The main advantage of pixel fusion is the saving of processing time. On one hand, the multispectral data process is quick. On the other hand, the landing runway can be detected at long range, in a large field of view.

APPLICATION OF ADVANCED SAFETY TECHNIQUE TO RING LASER GYRO INERTIAL NAVIGATION SYSTEM INTEGRATION

Blaylock, James, Lockheed-Fort Worth Co., USA; Swihart, Donald, Wright Lab., USA; Stribula, Chuck, Aeronautical Systems Div., USA; AGARD, Dual Usage in Military and Commercial Technology in Guidance and Control; Mar 1, 1995, 10 p; In English; See also 19950026705; Copyright; Avail: CASI; A02, Hardcopy; A02, Microfiche

This paper documents the application of System-Wide Integrity Management (SWIM) to the integration of H-423 and LN-93 ring laser gyro (RLG) inertial navigation system (INS) units with the F-16 terrain following (TF) system. Safety modeling and mishap rate predictions are presented for F-16 TF with an RLG INS. This paper establishes that the H-423 and LN-93 RLG INS units are both safer for F-16 TF than the predecessor LN-39 gimbaled, mechanical-gyro INS. The RLG INS design enhancements described are primarily built-in test (BIT) modifications that were developed as a result of the in-depth SWIM critical signal path analysis. These enhancements are low-cost design improvements to the RLG INS units because they were discovered prior to the manufacturer's final operational flight program (OFP) for the production units. This paper discusses dual-use applications of the RLG INS to other military and civilian functions, with design enhancements resulting from the SWIM process. Other military applications include not only specialized control modes such as TF, but also all other phases of the military flight operations regime, since the INS is always active to provide current aircraft state information. Civilian uses can also benefit from the SWIM process improvement to the RLG INS because accurate, reliable, safe navigation with critical timing along congested air routes, in weather, and in dense traffic terminal areas is of paramount importance for passenger safety.

The need for an up to date, comprehensive treatise on aerospace navigation systems has been recognized. It is anticipated that the target reader of this AGARDograph will be an individual who has the responsibility for the integration of navigation equipment aboard an aerospace vehicle. The AGARDograph is organized into six sections detailing the motivation for establishing the requirements to assure that the development of an aerospace navigation system will meet its operational requirement; reviewing the navigation coordinate frames with a discussion of inertial, terrestrial, and geodetic coordinate systems; describing modern navigation sensor technologies; addressing the system analysis and synthesis methods; representing state-of-the-art navigation system implementations in different aircraft; and describing various test methods used to verify the performance of aerospace navigation systems used in NATO countries.

COORDINATE FRAMES

Kumar, Muneendra, Defense Mapping Agency Systems Center, USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 7-41; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Accurate navigation requires an understanding of the three coordinate frames and systems which define positions in space. The first is the inertial frame in which the earth revolves around the sun annually. This annual motion is affected by the general precession and astronomic nutation and it takes place in the Earth Centered Inertial (ECI) frame or Conventional Inertial System (CIS). Second is the reference frame which is defined by the daily rotation of the earth around its polar axis. This Instantaneous Terrestrial System (ITS) frame requires knowledge of the sidereal time relationship with the CIS. Third frame is the geodetic or Earth Centered Earth fixed (ECEF) coordinate system defining the three-dimensional positions on the earth's surface or in its adjoining space. This frame is also known as Conventional Terrestrial System (CTS) and requires the knowledge of the earth's polar motion, the gravity field, and its size and shape. The ECI (or CIS) transformation to the ECEF (or CTS) frame makes use of the new theories of precession, astronomic nutation, change to a new J2000.0 Standard Time Epoch, the new definition of Universal Time as defined and adopted by the International Astronomical Union (IAU), and the latest ECEF frame, viz., Word Geodetic System (WGS) 1984. In the discussion that follows, all the coordinate frames or systems are right-handed and orthogonal, and positive rotation is clockwise when viewed from the origin towards the positive axis. Further, the three rotational matrices, $R(\text{sub } x)$, $R(\text{sub } y)$, and R represent the positive rotations about the orthogonal axes X, Y, and Z respectively.

INERTIAL NAVIGATION

Stieler, B., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 45-131; In English; See also 19960003395; Copyright; Avail: CASI; A05, Hardcopy; A04, Microfiche

Inertial navigation system (INS) provides all information about the kinematics of a vehicle, namely attitude and heading, ground speed and position, and also angular rate and acceleration independent of any sources of reference from outside. No question about its role for military aviation, marine navigation and for missiles. A high inertial technology is nowadays a trademark for military independent of many countries. Inertial navigation is also widespread in use in civil aviation and in space flight. Any large civil aircraft is equipped with two or three inertial navigation reference systems. The advent of the 'Global Navigation Satellite System (GNSS)' will in principle not change this situation in the time to come, especially under the consideration that a solution for its undisturbed availability in times of strained

political situations for the countries running the system is not yet in sight. This chapter is arranged in the following training of thoughts. The directional reference in an INS is explained with the mechanical gyro and stabilized platform as examples. It is symbolized by the weathercock in the functional diagram for a platform INS. The characteristics of the gyro-stabilized platform as directional reference serve to visualize the characteristics of the 'analytic platform' in the navigational computer of modern strapdown systems. Again this is symbolized in a weathercock, the functional diagram for a strapdown system. Directional references and their error characteristics are discussed. Accelerometers as sensors for measuring the translational motion are fairly simple instruments in principle, but the formula for their output signal on the rotating earth is lengthy and it is the basis for programming the navigational computer of an INS. These aspects are treated in Section 3. The integration of the accelerometer signal to ground speed and position and the control or computation of the directional reference is subject of the navigational computer. The interlinking of all signals within and INS causes error characteristics more benign than we would expect from our school learning. This is subject of Section 4. Also the INS for worldwide navigation, common features and differences of all mechanizations are discussed. The goal is to derive the error model appropriate for integrating the INS with the other sensors and systems discussed in this book. The main part of this chapter contains only general outline which are essential from the system point of view. Special features as coordinate systems for inertial navigation supplementing the chapter 'Navigation Coordinate Systems', digital data processing of inertial signals especially in strapdown systems, and optical gyros are treated in the appendices which are named correspondingly with C, D, and O.

DOPPLER RADAR NAVIGATION

Buell, Heinz, GEC-Marconi Electronic Systems Corp., USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 132-151; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The use of the Doppler principle to measure velocity has been underway since the early 1950's. The Doppler principle or effect has been applied to many systems in which velocity is an important variable. The discussion herein will concentrate on the use of a self-contained radar in an airborne vehicle to measure the velocity of that vehicle. Fixed-wing aircraft and helicopters have used Doppler radars successfully for many years, and drone aircraft and missiles are beginning to exploit the low cost and high reliability of Doppler radars.

TERRAIN REFERENCED NAVIGATION

Boozar, Drayton D., Sandia National Labs., USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 152-157; In English; See also 19960003395; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

Terrain referenced navigation is a technique for improving the accuracy of a navigation system by correlating a sensed elevation profile of terrain beneath a vehicle with stored terrain elevation data. Position estimates are referenced to the terrain data and are insensitive to position bias errors in the terrain data. Because of this characteristic, terrain referenced navigation systems are especially useful in applications that require accurate navigation relative to targets, obstacles, structures, and other features whose locations are derived from the same source as the stored elevation data. Example applications include low-emission terrain following/terrain avoidance, target queuing for standoff weapon terminal sensors, indirect ranging and ground proximity warning. System navigation accuracy depends primarily on the ratio of terrain roughness to terrain data vertical accuracy and secondarily on navigation system accuracy, vehicle ground clearance, ground cover, vehicle maneuvers, and update frequency.

Terrain referenced navigation systems are often considered for use with terrain masking for covert, low-altitude ingress into hostile areas. Low probability of intercept radar altimeters may be used in these applications. A key issue is the availability and quality of terrain elevation data. This chapter provides avionics system developers an overview of terrain referenced navigation system capabilities and characteristics, and an outlook for future applications.

AN OVERVIEW OF OMEGA RADIO NAVIGATION SYSTEM

Liang, David F., Directorate Research and Development Communications and Space, Canada; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 177-186; In English; See also 19960003395; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

Omega is a very low frequency (VLF) navigation system using frequencies allocated for radio navigation in the band between 10 KHz and 14 KHz. Such a low frequency band enables Omega navigation system to achieve the long operating ranges required for global coverage, at the same time provides a stable and predictable propagation environment. This also makes it the only radio navigation system applicable to completely submerged submarines. Omega is a hyperbolic position fixing system, the hyperbolae are loci of constant time difference between the arrival of signals from two transmitting stations. The time difference is measured as a difference in phase of the two received signals. Each hyperbola is known as a line of position (LOP). Signals must be received from at least three stations with one of them serving as a common station, to obtain a position fix from the two LOP's. The hyperbolic mode is attractive, since it removes the need to use a precise and expensive local oscillator. It is also possible to work with two stations using a circular mode, which requires a precision local oscillator. In such a case, the position fix is obtained from the intersection of circular rather than hyperbolic LOP's.

AGARDOGRAPH ON ADVANCED ASTROINERTIAL NAVIGATION SYSTEMS

Levine, Seymour, Northrop Corp., USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 187-199; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper discusses modern Strapdown Astrometric Navigation (SAIN) systems as autonomous navigators for manned aircraft, ships, missiles, and remotely piloted vehicles. These systems, which approach Global Positioning System (GPS) accuracy, do not depend upon man-made electromagnetic radiating devices that may be intentionally shut down, destroyed, or become unreliable in a hostile environment. The paper analyzes the gyroscopic accuracy, artificial stellar image stabilization, star density, sky visibility, and sky background irradiance effects on system performance. It concludes that a high-precision, reliable, low-cost stellar inertial system can be achieved by eliminating gimbals and combining a strapdown Inertial Navigation System (INS) with an Optical Wide-Angle-Lens Startracker (OWLS).

MAGNETIC HEADING REFERENCES

Moore, Donald L., Smiths Industries Aerospace and Defense Systems, Inc., USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 200-205; In English; See also 19960003395; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper addresses the most common system for providing aircraft heading reference: the magnetic heading reference system. It begins briefly explaining the importance of a magnetic heading reference. It then addresses the fundamental characteristics of the earth's magnetic field and explains the concept of 'magnetic variation'. It discusses two of the more common styles of magnetic heading sensors along with their inherent errors. After explaining how these different compasses operate, the paper explains the different types of heading errors that occur. Section 4 addresses the in-flight errors, while Section 5 addresses the magnetic disturbances caused by the aircraft itself. Section 6 discusses calibration techniques that provide for the correction against these magnetic disturbance induced errors. Finally, this paper concludes with a brief discussion of future trends.

AN OVERVIEW OF A GENERIC MULTI-SENSOR INTEGRATED NAVIGATION SYSTEM DESIGN

Liang, David F., Directorate Research and Development Communications and Space, Canada; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 210-230; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Modern avionics systems are becoming increasingly sophisticated as the demands for better mission performance and higher reliability continue to escalate. Many of the missions must be carried out at ultra-low altitude under all weather and visibility conditions. The increased range, speed and accuracy of modern weapon systems, impose stringent accuracy and reliability requirements upon the aircraft navigation system. To enhance mission success in a hostile environment, the pilot amongst other things needs to operate weapon systems, target acquisition and designation systems, radar detection, night vision systems and perhaps engage in air-to-air combat. This paper describes the application of Kalman filtering technology to the design and development of a multi-sensor Generic Integrated Navigation System (GINS).

DEEP INTEGRATION OF GPS, INS, SAR, AND OTHER SENSOR INFORMATION

Lewantowicz, Zdzislaw H., Wright Lab., USA; Paschall, Randall N., Wright Lab., USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 231-264; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

This discussion is presented in the context of avionics sensor integration methodology. However the concepts developed and illustrations presented are in no way limited in application to military avionics systems. There is a growing number of civil applications, where information from multiple sensors is combined to improve performance, provide redundancy management, increase robustness, or achieve graceful degradation when sensor failures (or outages) occur. We are rapidly moving beyond the classical examples of sensor information integration such as in aircraft navigation, or in control of chemical processes, nuclear plants, and jet engines. For example, the automotive industry is using several sensors for engine emissions and fuel control, vehicle active suspension, and yes, vehicle electronics (vetronics). Communication systems, position, velocity, and attitude (rotation) sensors, and other information are rapidly appearing in the consumer automobiles. These sensors provide, at affordable cost, functional capabilities, which until recently were reserved for the more expensive commercial air and ground systems. Other applications of sensor integration are either being implemented, prototyped, or considered in toys, electronics, consumer products, such as the household washers and dryers, communications, and home environment monitoring and control systems. Although the sensor integration possibilities are expanding into these other domains, this discussion focuses on deep integration of Global Posi-

tioning System (GPS), inertial navigation systems (INS), synthetic aperture radar (SAR), and other sensors which are a subset of modern aerospace systems.

19960003407 Draper (Charles Stark) Lab., Inc., Cambridge, MA, United States

GPS/INERTIAL INTEGRATION OVERVIEW

Greenspan, Richard L., Draper (Charles Stark) Lab., Inc., USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 281-294; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

GPS/Inertial integration is the process whereby a superior system navigation solution is produced by properly combining outputs from a GPS user equipment (UE) and from an inertial navigation system (INS). This process is receiving much attention because it is perceived to be a cost-effective means to satisfy navigation requirements that could not be met by either GPS or by an INS acting by itself. Some expectations levied on integrated systems are realistic; others, including hopes for mass-market commercial applications, will be delayed pending the development of suitable low-cost inertial technology. The technical basis for considering GPS/INS integration is the complementary nature of the navigation errors for each system operating stand-alone. The GPS solution is relatively noisy; the noise-driven variance of GPS positioning errors is on the order of a meter per axis, per position determination. However, GPS errors are bounded, whereas inertial navigation errors are dominated by a low-frequency component that grows in proportion to the mission duration. (The high-frequency content of inertial errors is very small, amounting to a few centimeters (rms) over tens of seconds.) One expects that an integrated navigation solution would perform like an inertial navigator whose errors were bounded by the GPS solution. This performance is actually achieved using one of the least aggressive approaches to integration; further benefits achieved using more aggressive integration options are discussed in the following sections.

19960003409 Litton Guidance and Control Systems, Woodland Hills, CA, United States

VERTICAL CHANNEL DESIGN CONSIDERATIONS

Ausman, J. Stanley, Litton Guidance and Control Systems, USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 312-327; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The vertical channel of an inertial system is unstable. This instability is caused by the gravity compensation fed back to the vertical accelerometer output. The gravity compensation, computed as a function of altitude after doubly integrating the output of that accelerometer, creates an unstable, positive feedback loop. The time constant of this instability is about 560 seconds near the earth's surface. For ballistic missiles and rockets this does not pose a problem because the guidance is completed before the instability becomes serious. For aircraft systems, however, one must augment the inertial measurements, typically with barometric altimeter information, in order to stabilize the vertical inertial channel. Earliest mechanizations of the baro-inertial loop employed second-order feedback with constant gains. The next step was to add integral feedback in order to bias the vertical accelerometer, thus creating a third-order system. Widnall and Sinha investigated the third-order loop to find the optimum set of fixed gains. Not surprisingly, they found that the optimum set of gains depended on the values assumed for the noise characteristics of the accelerometer and the barometric altimeter. Because the noise magnitudes will vary as a function of the aircraft's flight regime, the baro-inertial feedback gains should not be constant, but should also vary. Litton first mechanized a third-order variable gain baro-inertial loop in CLASS, in all-weather close air support system, successfully demonstrated in 1972. They gradually improved upon that basic design over the years as successive systems, principally ARIS, uncovered more and more barometric altitude error characteristics which had to be accommodated. The culmination of this evolutionary development is the baro-inertial loop currently mechanized in the LN-93 and LN-94 systems for the USAF

Standard RLG INU. Following a discussion of barometric and inertial errors, we will take a detailed look at the LN-93/94 conventional vertical channel mechanization, the reasons behind the loop design, and some simulation results illustrating the loop performance when subjected to certain flight maneuvers and barometric errors.

REPRESENTATIVE VEHICLE IMPLEMENTATION: ROTARY WING AIRCRAFT

Niemela, John, Army Communications-Electronics Command, USA; Liang, David F., Directorate Research and Development Communications and Space, Canada; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 381-389; In English; See also 19960003395; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

Rotary wing aircraft have seen an ever expanding role in support of land and sea military operations including: search and rescue, scout, attack, troop transport, anti-submarine warfare, anti-surface ship targeting, cargo and electronic warfare. They are ideally suited for operation in confined and unprepared areas where no other form of aerial transport is suitable. For a helicopter to survive on the modern battlefield, flight profiles are mandated that impose unique requirements on the navigation system. These include contour and nap-of-the-earth flight as well as hover in defile in close proximity to obstructions. Critical mission segments are conducted in nap-of-the-earth flight during which the pilot conceals the helicopter with terrain, foliage and buildings. These missions must be accomplished in all weather and visibility conditions. In the course of these missions, the rotary wing aircraft crew must maintain accurate self-location to maintain geographic orientation and situational awareness relative to friendly and hostile forces. A typical tactical mission profile overlaid on a contour map is shown, illustrating the non-linear flight path which takes advantage of terrain masking. For the anti-submarine warfare missions the helicopter navigation system must maintain stable and accurate tactical plots over long periods of time. In the anti-surface ship targeting role, a high degree of absolute and relative navigational accuracy are vital to rapid and successful action. There are further complicating factors as well. Operations must often take place under radio silence and shore-based or satellite navigation aids may be destroyed or jammed during wartime. The small crew of the helicopter must not be burdened with monitoring the functioning of, or updating, the navigation system.

This section of the document describes the various methods employed to evaluate the performance of aerospace navigation systems. Included are discussions regarding test equipment, test data, reference systems, environmental conditions, laboratory tests, flight test profiles and procedures, and statistical methods used to measure system performance. The test methods detailed in this document are somewhat specific and may need to be adapted to particular systems and their specifications.

Knowledge-Based Functions in Aerospace Systems; Nov 1, 1995, 31 p; In English; See also 19960012290; Avail: CASI; A03, Hardcopy; A02, Microfiche

This paper presents design principles and algorithm for building a real time scheduler. The primary objective of the scheduler is to assign arrival aircraft to a favorable landing runway and schedule them to land at times that minimize delays. A further objective of the scheduler is to allocate delays between high altitude airspace far from the airport and low altitude airspace near the airport. A method of delay allocation is described that minimizes the average operating cost in the presence of errors in controlling aircraft to a specified landing time.

Voelckers, Uwe, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Boehme, D., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Knowledge-Based Functions in Aerospace Systems; Nov 1, 1995, 18 p; In English; See also 19960012290; Avail: CASI; A03, Hardcopy; A02, Microfiche

Air Traffic Management (ATM) is a very complex and challenging domain. To cope with future traffic demand, while still maintaining or even increasing safety and efficiency of air traffic operations, intelligent machine functions have to be developed to assist the human operators in their mental control tasks. The specific requirements of the ATM domain necessitate sophisticated and well-designed assistance tools. Their most significant characteristics, design principles and structures are discussed and exemplified in a real-world application.

SIMULATION MODELS FOR IFF SYSTEM PERFORMANCE ANALYSIS

Walberer, A., Elektroniksystem- und Logistik G.m.B.H., Germany; Oct. 1995; 10p; In English; See also 19960016897; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Identification Friend or Foe (IFF) is an important means of air traffic surveillance for military air operation. Due to this fact, several studies of IFF equipment were conducted in the past, to assist the analysis of IFF system performance, two simulation models have been developed at 'Elektroniksystem- und Logistik GmbH' in Munich, Germany. The description of these models is the main subject of this paper. The first model is based on a probabilistic methodology. It operates on a scenario reflecting the environment to be considered. The model determines the interrogation rates at each transponder deployed in the environment. Applying the probability theory, the behavior of the transponders is predicted and their reply rates are obtained. The reply rates are the input for the calculation of the signal loads at the interrogators and the establishment of their behavior. The second model is designed as a discrete-event simulation model. At each point in time an interrogation is generated, the arrival times and the power levels of the interrogation at the transponders are determined. The processing of the interrogation by the transponders is modelled by taking into account the various interference mechanisms. If a reply is challenged by an interrogation, the arrival times and the signal power levels at the interrogators are calculated. Interferences with the reply are checked in order to establish the proper evaluation of the signal by the interrogator.

Over 25 years, the Guidance and Control Panel of the Advisory Group for Aerospace Research and Development to the North Atlantic Treaty Organization has devoted part of its activities to the fascinating field known historically as Air Traffic Control, covering also Air Traffic Management, and more generally Air Traffic Handling. This Report provides a list of the summaries of the papers which were presented at the symposia and included in the AGARDographs devoted to this wide and most challenging subject, covering essentially, Air Traffic Control Systems (1972); A Survey of Modern Air Traffic Control, Vols. 1 and 2 (1975); Plans and Developments for Air Traffic Systems (1975); Air Traffic Management (1979); Air Traffic Control in Face of Users' Demand and Economy Constraints (1982); Efficient Conduct of Individual Flights and Air Traffic (1986); Aircraft Trajectories, Vols. 1, 2 and 3 (1990); Machine Intelligence in Air Traffic Management (1993); and On-Line Handling of Air Traffic (1994). The Report is completed by two indexes, an extended subject Index, and an Authors and Contributors Index.

MEASUREMENTS OF GPS AND LORAN PERFORMANCE IN AN URBAN ENVIRONMENT

Miller, Lance C., Science Applications International Corp., USA; Vaurio, David, Science Applications International Corp., USA; Giambalvo, Albert, Science Applications International Corp., USA; Karp, Sherman, Science Applications International Corp., USA; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 10p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

During the summer of 1994, the Advanced Research Projects Agency funded an experiment to collect extensive radionavigation data in the New York City area. The participants are listed under the Acknowledgments. The data includes the accuracy and availability of the Global Positioning System (GPS) and LORAN-C, the increased availability of both GPS and LORAN by adding a precise oscillator input to the receivers, and a comparison of electric field (E-field) and magnetic field (H-field) LORAN signal availabilities. Analysis of the data shows: (1) in the deep urban canyons of Wall Street, the availability of LORAN (either E or H field) is higher than that of GPS; (2) in almost all scenarios, the LORAN magnetic field signal is easily detectable and has repeatable phase characteristics. In contrast, the LORAN electric field signal strength is frequently attenuated and undetectable, especially in the Wall Street area and under the elevated train tracks in the Bronx; (3) when corrected for propagation anomalies, the inherent repeatable accuracy of LORAN is 7-10 meters rms with under 100 meters rms potentially obtainable in an operational differential mode; and (4) the availability of radionavigation fixes can be enhanced in these urban areas by the integration of LORAN and GPS navigation information and by the use of a precise oscillator which allows a geographic fix to be made by receiving as few as two time of arrival broadcasts, e.g. one GPS satellite and one LORAN station.

This paper describes our low power microwave coupling measurements on hand-held GPS (Global Positioning System) receivers in the frequency range between 0.3...2 GHz. The plane wave excitation experiments have been carried out mainly in our field coupling facility, which consists of an asymmetric triplate transmission line with maximum CW field levels of up to 120 V/m at the test position. As test objects we examined four Standard Positioning Service (SPS) C/A-code GPS receivers of different manufacturers. The test objects were positioned in the simulator in three orthogonal orientations with respect to the external field. To maintain a high-integrity navigation, the GPS receiver must maintain lock on the satellite signal and read the data. A three dimensional position (latitude, longitude and altitude) at least requires four satellites to be in view. Failure is defined when this 3 D fix is lost. It turned out that the GPS were most susceptible to CW fields with its internal antenna. They were less susceptible if the receiver and the GPS antenna were placed separately and linked together via a cable. Worst case effects caused GPS switch off, but no damage occurred at field strengths below 100 V/m at out-of-band frequencies. Pulse testing (width = 20 microns) the GPS always required much higher fields to cause upsets depending strongly on frequency and test object. In some cases pulsed fields of more than 2 kV/m were necessary.

The Global Positioning Satellite System (GPS) is now operational and GLONASS will soon be declared operational. Meanwhile, INMARSAT has announced its intent to expand its services to include navigation signals broadcast from geostationary satellites, and several industrial organizations plan to provide commercial, satellite-based, navigation services. With prospects for reliable worldwide service becoming a reality, the technical and financial barriers to innovative applications are being overcome. This Lecture Series will provide an appreciation of the technical, operational and performance features of satellite-based navigation including the signal-in-space and the user equipment for GPS, GLONASS, and integrated GPS/GLONASS implementations; assessment of the quality of service that has been achieved and an introduction to projected service enhancements. The introductory lecture will provide an overview of Satellite based navigation and some of the imaginative uses to which it has already been put. The application of satellite signals to precision approach and landing for civil aviation and for the determination of vehicle attitude (orientation) will be featured in the following lectures. Other topics include quality monitoring of user's navigation solutions, the integration of satellite navigation with inertial measurements and high-precision relative and differential positioning. This Lecture Series, sponsored by the Mission Systems Panel of AGARD, has been implemented by the Consultant and Exchange Program.

The Global Navigation Satellite System (GNSS) is the visionary goal for a world-wide utility that will ultimately provide reliable and dependable navigation and timing services to civil and national users. The enabling technology is firmly rooted in operational satellite navigation systems that have been developed for military use, including the Global Positioning Satellite System (GPS) and the Global Navigational Satellite System (GLONASS) developed in the USA and Russia respectively. However, the rapid acceptance into operational use by the civil community of even the degraded performance levels that have already been made available has exposed the need for additional features of the existing signals to deliver improved services. Although these additional features will be provided initially as augmentations to the existing systems, the GNSS, in whatever form it eventually takes, remains the end point toward which governments, international service providers, industry and user groups are planning. This introductory lecture provides an overview of the means by which individual design features of satellite navigation systems are seen to satisfy the mission requirements for specific user groups, and it sets the context for the other presentations in this lecture series. This presentation is organized from the viewpoint of the users of the satellite navigation services; it also includes a review of some applications of these services that were not even remotely anticipated by their original designers. Most of this discussion is based on the Global Positioning Satellite System.

The Russian Global Navigation Satellite System (GLONASS) is a space-based positioning, velocity and time system. In this lecture the evolution of GLONASS towards operational status is presented. The operational constellation, the constellation maintenance plan and replenishment policy, coverage and dilution of precision factors are described along with the Russian national policy for user access to the service. The lecture addresses the characteristics of GLONASS broadcast signals in space including modulation techniques, code structure, message content and formats, navigational accuracy achieved by GLONASS users, differential technique, user equipment performance, future GLONASS upgrades and applications of GLONASS in the Commonwealth of Independent States are described.

Integrated Global Positioning System/Global Satellite Navigation Systems (GPS/GLONASS) receivers offer better availability, performance, and integrity than GPS only receivers. In this lecture, the GPS and GLONASS systems are compared and the advantages and difficulties associated with their combined use are discussed. The 3S Navigation R-100 series of receivers is used as a model to discuss the various receiver components and functions, including the antenna, RF/IF unit, tracking module, measurement generation and navigation

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION

solution generation. The R-100 architecture is described as well as that of the GNSS-200 which is more compact and the latest GPS/GLONASS receiver produced by 3S Navigation. Air, sea and ground results are presented. These include results for both the R-100 series as well as the GNSS-200. Stand-alone as well as differential performance are discussed.

NAVIGATION ACCURACY FOR ABSOLUTE POSITIONING

Lachapelle, Gerard, Calgary Univ., Canada; Jun. 1996; 10p; In English; See also 19960042824; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The real-time absolute (i.e., single point, stand-alone) accuracy achievable with the Global Positioning System (GPS) is a function of the User Equivalent Range Error (UERE) and the Dilution of Precision (DOP). The later parameter is a function of satellite geometry. The various error components affecting the magnitude of the UERE are quantified. They include satellite, atmospheric, and receiver dependent errors. The DOP's expected under ideal operational conditions are a function of space and time. The absolute accuracies currently specified for the Standard Positioning Service (SPS) and the Precise Positioning Service (PPS) are described. Various experiments conducted in recent years show that the actual PPS accuracy performance usually exceeds the specified level. Potential PPS accuracy enhancements which comprise satellite clock and ephemeris error reduction, tropospheric error reduction and receiver noise and multipath reduction are described. Recent tests by the 50th Space Wing of the US Air Force to reduce satellite clock and ephemeris errors show an improvement of nearly 50% in absolute positioning accuracy using current Y-code receiver technology. As a military application example, a comparison of the NATO STANAG 2373 artillery survey requirements with PPS accuracies shows that the artillery positioning requirement can be met under ideal satellite geometry with the currently specified PPS accuracy. Future PPS accuracy enhancements show that the artillery positioning requirements could be met under severely degraded satellite geometry, which is a more realistic scenario, given the concealment requirements for artillery. Selected recommendations of an independent study mandated by the US Congress and conducted by the National Academy of Public Administration and the National Research Council pertaining to both PPS and SPS enhancements are presented. Finally, the impact of the worldwide civilian GPS tracking network deployed by the International GPS Service for Geodynamics on post-mission absolute accuracy is discussed. The use of post-mission precise orbits and 30-second satellite clock corrections are resulting in absolute kinematic accuracies at the 1-3 m accuracy level using civilian receivers. The potential for this post-mission information to become available in real-time is mentioned.

RELATIVE AND DIFFERENTIAL GPS

Phillips, Richard E., Draper (Charles Stark) Lab., Inc., USA; Schmidt, George T., Draper (Charles Stark) Lab., Inc., USA; Jun. 1996; 22p; In English; See also 19960042824; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Many aerospace vehicles will have an avionics suite that includes an integrated inertial navigation system/Global Positioning System (INS/GPS) set. This means of navigation motivates examination of whether high accuracy (approx. equals 10 ft Circle of Equal Probability (CEP)) may be obtainable using only this set of weapon avionics operating in a relative or differential GPS mode, rather than in an absolute GPS mode where CEP's of 30 to 40 feet would be expected. This paper will explain how 10 ft accuracy may be achieved and it will present several different concepts that exploit such a capability. Fundamentally, two problems must be solved to achieve an accuracy of 10 ft: (1) destination or 'target' location must be determined to better

than 10 ft, and (2) the GPS/INS 'user vehicle' must be guided accurately to better than 10 ft. This paper will explain how the use of relative GPS can solve the guidance problem and how the use of relative targeting in a GPS based coordinate system can solve the target location problem. The use of differential GPS will also be discussed. The paper begins with a discussion of relative GPS and reports the results of actual experiments to determine accuracy degradation of relative GPS guidance systems as a function of baseline length and targeting latency. Various baseline lengths and latencies are considered showing that relative (or differential) GPS guidance may achieve high accuracy over baselines and latencies useful for various applications. Appendix A shows that to first order, relative and differential GPS systems give the same accuracy. Next, the target location part of the problem is addressed. There must be an accurate sensor that locates the target relative to the GPS reference receiver. The sensor may be either on the vehicle carrying the receiver or at a remote location. The reference receiver could either be on the surveillance aircraft or on the ground. If on the ground, both it and the target could have been located prior to the mission. Real-time target location concepts that will be explained include the use of aircraft equipped with an INS/GPS/Synthetic Aperture Radar (SAR) avionics suite to perform a real-time relative targeting function. The importance of reasonable aircraft maneuvers to enhance observability and speed up the three dimensional (3-D) target determination solution will also be addressed. Simulation results for several realistic scenarios will be presented. An example of an INS/GPS equipped guided parafoil for supply delivery will be discussed as one of the relative (or differential) GPS applications. Next, several concepts will be discussed that make use of highly accurate pre-mission relative target positioning, i.e., the ability to specify the 3-D location of two points, or localized areas, on the Earth relative to each other in a suitable reference frame such as WGS-84. It is of interest to speculate how such a capability could be exploited. Scenarios involving several existing or planned systems will be described. A detailed design example of an INS/GPS guidance system for a munition fired from a gun will then be presented. A final section will then discuss some of the practical issues in using relative (or differential) GPS.

REQUIREMENTS ON GNSS FOR CIVIL NAVIGATION

vanGraas, F., Ohio Univ., USA; Jun. 1996; 8p; In English; See also 19960042824; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The civil aviation community has had decades of experience in regulating the quality of land-based navigation aids and developing the procedures for their use that guarantee safe operation. The drafting of these principles and procedures into standards for satellite-based navigation aids has now been underway for more than a decade. This lecture will trace the evolution towards internationally-accepted definitions of 'required navigation performance' including accuracy, integrity, continuity, and availability considerations. Inasmuch as this is an on-going activity, the lecture will include a road map for the completion of actions that are underway.

Providers of a global navigation satellite system (GNSS) service will be required to demonstrate that users of their service will be informed within a limited time (now set at ten seconds for terminal area navigation and non-precision approach) of any satellite that fails to operate within its range of acceptable signal quality. The lecture will describe approaches to provide this 'integrity' feature including

receiver autonomous integrity monitoring (RAIM) as well as systematic approaches that involve augmentations of the navigation satellite constellation. Prominent among these is the wide area augmentation system for the Global Positioning System (GPS).

GNSS AUGMENTATION FOR HIGH PRECISION NAVIGATION SERVICES

vanGraas, F., Ohio Univ., USA; Jun. 1996; 14p; In English; See also 19960042824; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The absolute positioning accuracy of current or planned global navigation satellite system (GNSS) services is not good enough to support Category 3 precision approach and landing requirements, nor is it good enough to support high precision survey applications. The leading solution to this problem is to augment the basic service, the survey community has developed relative positioning techniques based on continuously tracked carrier phase measurements. A static or dynamic user compares accumulated carrier phase measurements to a specific set of satellites with simultaneous measurements taken by a reference receiver at a well surveyed location. The civil aviation community is also exploring 'local area' differential (GPS) concepts in which one or more reference beacons augment the satellite beacons in the vicinity of an airport. The lecture will identify the leading candidates for these augmentations and will characterize predicted performance improvements, and will present results of recent flight tests.

An inertial navigation system exhibits relatively low noise from second to second but tends to drift over time. Typical aircraft inertial navigation errors grow at rates between one and ten nautical miles per hour (1.8 to 18 km/hr) of operation. In contrast global navigation satellite system (GNSS) errors are relatively noisy from second to second but exhibit no long term drift. Using both of these sensors is superior to using either alone. Integrating the information from each sensor results in a navigation system which operates like a drift free INS. There are further benefits to be gained depending on the level at which the information is combined. This presentation will focus on integration architectures including 'loosely coupled' and 'tightly coupled' configurations. The advantages and disadvantages of each level of integration is listed. Examples of current and future systems will be cited. A performance comparison of 'loosely coupled' and 'tightly coupled' systems will be made. Navigation applications for which integration is essential will be given.

ATTITUDE DETERMINATION

Lachapelle, Gerard, Calgary Univ., Canada; Jun. 1996; 16p; In English; See also 19960042824; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The fundamental concept of precise attitude determination with multi-antenna Global Positioning System (GPS) receiver technology is described. The characteristics of the observable used for this purpose, namely the carrier phase, are summarized with emphasis on phase noise and multipath which constitute the major error sources. Given a multi-antenna configuration mounted on a rigid platform, the

procedure to successively fix the double difference integer carrier phase ambiguity between the nearby antennas, obtain sub cm-level tri-dimensional relative position vectors and transform them into the attitude components, namely roll, pitch, and heading, is described. The two-antenna case, which allows pitch and heading determination, is presented as a special case. Integer ambiguity resolution between the antennas turns out to be relatively easy to achieve with single frequency (L sub 1) data because the differential orbital and atmospheric errors are negligible and the fixed distances can be used as constraints to speed up the ambiguity resolution process. The use of various antenna configurations to recover the carrier phase ambiguities instantaneously is mentioned. The attitude accuracy is a function of several parameters, namely satellite configuration, inter-antenna separation, phase noise and prevailing multipath conditions. Two multi-antenna hardware approaches to the problem of attitude determination are described using various case studies, namely a dedicated multi-antenna receiver approach which allows real-time operation and a multi-GPS sensor approach which can be used in real-time only if the data from each sensor is transferred to a central processor as the measurements are made. If post-mission results only are required, no data links involving the sensors are required since the phase measurements can be precisely synchronized using the time obtained from the code measurements. The effect of signal masking on attitude determination, which is relatively severe due to the carrier phase ambiguity problem is discussed. The effect of relative platform motion, e.g., wing flexure in the case of an aircraft, on attitude determination performance is discussed. The case studies used deal with shipborne, aircraft, and land cases. The results with several multi-antenna systems deployed in various configurations are presented.

Many weapons and weapon carriers will have an avionics suite that includes an integrated inertial navigation system/global positioning system (INS/GPS) set. This means of navigation motivates examination of whether very high accuracy (about 10 ft) circular error probable (CEP) may be obtainable using only this set of weapon avionics operating in a relative GPS mode, rather than in an absolute GPS mode where CEPs of 30 to 40 ft would be expected. This paper will explain how 10 ft accuracy may be achieved and it presents several different weapon system concepts that exploit such a capability to rapidly attack targets.

CARRIER PHASE GPS TIME, SPACE, POSITION INFORMATION DEMONSTRATION (CAPTIDE)

Costabile, Gregg D., Department of the Air Force, USA; Fowler, Jesse, Department of the Air Force, USA; Elbert, Timothy, Department of the Air Force, USA; Reiter, David, III, Department of the Air Force, USA; Jun. 1996; 8p; In English; See also 19960053042; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

This paper presents a discussion and results of a flight test to obtain time, space, position information (TSPI) using a carrier phase (or kinematic) global positioning system (GPS). A carrier phase capable GPS receiver was installed on board an F-16 aircraft and flown in conjunction with an inertial navigation system (INS)/differential GPS guided weapon test program. The carrier phase TSPI data was compared to the position solution from existing test range TSPI sources, including: four high dynamic Contraves cinetheodolites operated at 30 frames per second, two FPS-16 radars, the aircraft position system solution, an INS/GPS position measurement pod on board the

aircraft, and a post-mission Kalman smoother based software algorithm called 'test data optimal processor'. The carrier phase and range solutions were also compared to the INS/differential global positioning system (DGPS) test items. A series of aircraft maneuvers were conducted to collect truth data to compare the carrier phase GPS position with the 'truth' position. This was the first experiment known to the authors which utilized the carrier phase observable in an aircraft environment where high accuracy TSPI was available to evaluate the accuracy of the carrier phase technology.

EXPLOITATION OF DIFFERENTIAL GPS FOR GUIDANCE ENHANCEMENT (EDGE) HIGH GEAR PROGRAM

Dargan, John L., Aeronautical Systems Div., USA; Howell, Gary, Aeronautical Systems Div., USA; Elbert, Tim, Aeronautical Systems Div., USA; Gaskill, David, Aeronautical Systems Div., USA; Jun. 1996; 12p; In English; See also 19960053042; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

On May 23, 1995, an F-16 dropped a modified GBU-15 incorporating a differentially corrected inertial navigation system/global positioning system (INS/GPS) to successfully attack a vertical target. The GBU-15 impacted within 2 meters of the target. The exploitation of differential GPS for guidance enhancement (EDGE) program allows streamlined acquisition and reporting procedures for adding a precision capability to baseline GPS-guided munitions. The EDGE program objective was to demonstrate the navigational accuracy improvement potential of differential GPS (DGPS) for guiding air-to-ground munitions through an end-to-end weapon system implementation of DGPS. Results show that precision navigation accuracy is attainable through DGPS. This paper provides details on the EDGE system implementation and the results from ground, captive, and free-flight tests.

NAVIGATION WITHOUT INITIALIZATION OF AN INERTIALLY GUIDED BOMB NAVIGATION SANS INITIALISATION D'UNE BOMBE GUIDEE INERTIELLEMENT

Paturel, Yves, Societe de Fabrication d'Instruments de Mesure, France; Martin, Eric, Societe de Fabrication d'Instruments de Mesure, France; Audren, Jean-Thierry, Societe de Fabrication d'Instruments de Mesure, France; Technologies for Precision Air Strike Operations in Rapid-Reaction and Localized-Conflict Scenarios; Jun. 1996; 10p; In French; See also 19960053042; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The range of traditional guided bombs is limited to 4 to 6 kilometers depending on the firing conditions. The sophistication of air defenses makes bombing missions more and more dangerous for pilots and their aircraft. The use of propelled bombs allows one to increase the range of bombs and therefore to ensure better mission safety. Obtaining accurate precision requires a means of guidance of which the most secure and most independent is inertial guidance. However, such guidance requires initialization of the inertial fusing of the bomb and therefore the supply of data from the aircraft to the bomb (speed, position). This constraint was expensive for earlier models of aircraft for which the numerical data links do not reach the inertial points of the bombs. This article succinctly describes a new technique which allows one to drop a propelled bomb, and guide it with out initializing the inertial mechanism. An analysis of performance features of the process was simulated as well as an analysis of the sensitivity to different error sources. The modifications required for aircraft flight control are described.

A SIMULATION-BASED STUDY OF THE IMPACT OF AIRCRAFT WAKE TURBULENCE WEIGHT CATEGORIES ON AIRPORT CAPACITY

Robinson, Jerry J., Boeing Commercial Airplane Co., USA; Nov. 1996; 16p; In English; See also 19970014096; Original contains color illustrations; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The Federal Aviation Administration (FAA) is considering revising the current aircraft wake turbulence weight categories and the associated separation standards during instrument meteorological conditions (IMC). Various proposals have been submitted to the FAA with regard to this revision. This paper presents the results and conclusions of a capacity study conducted by The Boeing Company. This study examined the impact of these proposed changes on airport capacity during IMC. The approach taken for this study was to simulate arrival and departure operations at ten major US airports by employing a database derived from the 1993 Official Airline Guide (OAG) traffic schedule. Simulations were conducted for the traffic mix at each airport utilizing one standard, representative runway configuration. The aircraft wake vortex separation requirements were changed according to the various proposed weight categories; these separations were then applied to the particular traffic set at each airport. In general, it was found that current capacity levels could be reduced by as much as 4%. This approach provides a consistent comparison of capacity results. It is hoped that the results from this study will provide useful information to assist in assessing the capacity impact of a modification to the existing aircraft wake turbulence weight categories and their associated separation standards during IMC.

AN AIRCRAFT VORTEX SPACING SYSTEM (AVOSS) FOR DYNAMICAL WAKE VORTEX SPACING CRITERIA

Hinton, D. A., NASA Langley Research Center, USA; Nov. 1996; 12p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A concept is presented for the development and implementation of a prototype Aircraft Vortex Spacing System (AVOSS). The purpose of the AVOSS is to use current and short-term predictions of the atmospheric state in approach and departure corridors to provide, to ATC facilities, dynamical weather dependent separation criteria with adequate stability and lead time for use in establishing arrival scheduling. The AVOSS will accomplish this task through a combination of wake vortex transport and decay predictions, weather state knowledge, defined aircraft operational procedures and corridors, and wake

vortex safety sensors. Work is currently underway to address the critical disciplines and knowledge needs so as to implement and demonstrate a prototype AVOSS in the 1999/2000 time frame.

PRECISION TERMINAL GUIDANCE FOR MUNITIONS LE GUIDAGE TERMINAL PRECIS POUR LES MUNITIONS

Feb. 1997; 136p; In English

Report No.(s): AGARD-AR-342; ISBN 92-836-1048-2; Copyright Waived; Avail: CASI; A07, Hardcopy; A02, Microfiche

The effectiveness of the guided munitions used in that conflict emphasized their importance in 'conventional' warfare. Following this experience, the lessons learned from military interventions by NATO nations has often yielded less clear-cut results. In spite of these recent events, it seems clear that the future of precision guidance is assured, for reasons similar to those prevailing during the Gulf War, that is, their usefulness as a 'force multiplier'. This enables them to: maximize the effective fire power of launch platforms; minimize the number of missions required to carry out a given task; and reduce collateral damage to non-combatants to a minimum. The Working Group oriented its aims towards NATO military needs and the review of terminal guidance technology in relation to those needs, using the two following items as a starting point: the AGARD planning guidelines, which give a top-down view, derived from the NATO strategic concept; an analysis by GCP of the implications of the Gulf War for guidance and control. The review of terminal guidance technologies was also aimed at identifying new capabilities not currently part of NATO's armory. Projections into the future often produce speculative concepts that, in the light of deeper study, turn out to be unworkable, unaffordable or even misguided. But new ideas, however impractical at first sight, are the stimulus NATO needs to stay at the forefront of technology advances.

A NAVIGATION SYSTEM CONCEPT FOR A MODERN ANTI-SHIP MISSILE

Hoelsaeter, O., Norwegian Defence Research Establishment, Norway; Jalving, B., Norwegian Defence Research Establishment, Norway; Nov. 1996; 12p; In English; See also 19970018626; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A navigation system concept for a modern anti-ship missile has been investigated. The navigation system can be divided into several subsystems. At open sea, altitude measurements are used in a Kalman filter to limit the inertial navigation system (INS) error propagation. Correspondingly, terrain contour matching (TERCOM) position updates are used when flying over land. A method for estimating the sea state and predicting extreme wave heights, which is useful in choosing sea skimming altitude, is also discussed. Finally, a model based compensator, which reduces dynamic errors of the INS attitude references used for seeker stabilization, is described. The paper presents the theory of the various subsystems and how they are integrated. Results from tests with real data as well as simulations are presented.

The Advanced Research Projects Agency (ARPA) began a program in May 1983 to demonstrate the necessary solid-state technologies to miniaturize full military precision (P/Y) GPS receivers.

The 'Virginia Slims' miniature GPS receiver (MGR) program was successfully completed in December 1989 with the demonstration of an MGR the size of a cigarette package. Military products derived from the 'Virginia Slims' MGR chip set include the Tomahawk Land Attack Missile GPS receiver, the Precision Location GPS Receiver (PLGR), and the Miniature Airborne GPS Receiver (MAGR), as well as several commercial GPS engines.

HIGH INTEGRITY GLOBAL PRECISION NAVIGATION SYSTEMS

Schmidt, George T., Draper (Charles Stark) Lab., Inc., USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 16p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

This paper will focus on the technology trends for (1) inertial sensors, (2) GPS accuracies, and (3) integrated GPS/INS systems, including considerations of jamming, for military platforms and weapons, that will lead to the high integrity, one meter accuracy global precision navigation systems of the future. For inertial sensors, trend-setting sensor technologies applicable to military systems will be described. They are: fiber-optic gyros, silicon micromechanical gyros, resonating beam accelerometers, and silicon micromechanical accelerometers. A vision of the inertial sensor instrument field, and inertial systems for military applications for the next few decades will be given. GPS specified and observed current accuracies will be described, as well as, planned accuracy improvements due to various stages of the WAGE implementation, inter-satellite ranging, and "all-in-view" tracking. Uses of relative and differential GPS will be discussed. The trend towards tightly-coupled GPS/INS, where both code and carrier tracking loops are aided with inertial sensor information, will be described and the synergistic benefits explored. Some examples of the effects of jamming will be described and expected technology trends to improve system anti-jam capability will be presented.

SYTRAM (SYSTEME DE TRAJECTOGRAPHIE MULTIMOBILE): A NEW GUIDANCE METHOD FOR TEST OF MULTITARGET AIRPLANES SYTRAM (SYSTEME DE TRAJECTOGRAPHIE MULTIMOBILE): UNE NOUVELLE METHODE DE GUIDAGE DES AVIONS POUR LES ESSAIS MULTI-CIBLES

DeMalleray, E., Centre d'Essais en Vol, France; Advances in Flight Testing; Dec. 1997; 16p; In French; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

SYTRAM has been developed based on a need by CEV (Centre d'Essais en Vol) to have an autonomous and precise guidance system for multi target testing. The multi target tests often require the development of precise scenarios that are difficult and even impossible without a high quality and continuous guidance system. Until now, these tests have been conducted with the assistance of guidance systems on the ground, transmitting their orders via radio. They can only follow one airplane with precision, and up to a maximum of 4 airplanes. Beyond that, several guiding systems would be necessary, but the radio would be saturated. SYTRAM is an ascending and descending liaison. The ascending liaison (60 KBIT/sec) of the system SYTRAM allows the conception of a function, named "Autonomous Guidance" which will produce guidance information to the equipment being tested, for autonomous installation, i.e. without the use of radiotelegraphy. Four guidance interfaces have been developed, the HUD, the HDD, and the Classic and Audio Instrumentations. The guidance law, common to all interfaces, was completed in the simulator in 3 weeks. In flight tests started with 3 flights on the ABE Mystere XX. The goal of these tests was to confirm the feasibility of the autonomous guidance function. The interface HDD was chosen for the tests but the capacity to modify the coefficients of the law of in-flight navigation was preserved. Finally, the application of the HDD symbology is under development on a liquid crystal screen.

Garcia, European Organization for the Safety of Air Navigation, Belgium; Swierstra, S., European Organization for the Safety of Air Navigation, Belgium; Advances in Flight Testing; Dec. 1997; 10p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Over the years a continuing increase in demand for air travel was observed that always surpassed the highest estimates. The capacity limit of the major airports constitutes one of the bottlenecks in the expansion of air transport. In order to maintain a competitive edge, air carriers use aircraft types that offer optimum economy on the routes they fly. In a typical hub operation, this results in a mixture of jet, turbo-prop and prop aircraft, each with a different operational speed range. Today for the main airports, the runway constitutes a major bottleneck. Accordingly the optimisation of the capacity of an airport becomes a very complex task when the stream of inbound aircraft consists of a mixture of aircraft types. The introduction of automated tools to enhance the efficiency of the air traffic controllers is one of the targets of the EATCHIP programme to improve the overall quality of the air traffic control services provided. Research programmes have led to the development of such tools, in particular to assist the air traffic controllers with the problem of optimum Arrivals Management. Meanwhile these tools have been tested and initially validated in simulation environments. The requirement existed to test and demonstrate algorithms developed using a real aircraft, initially in an isolated, well-controlled flight environment. This has led the EUROCONTROL Agency (EHQ, Brussels) and the Instituto Superior Tecnico (IST, Lisbon) to organize in close co-operation with Aeroportos e Navegacao Aerea (ANA, Lisbon) and Montijo a live exercise to investigate the feasibility and performance of such a tool. This report describes the flight trials and some of the conclusions drawn. The references at the end of this text give a detail explanation of the different components that were used to perform these trials.

ENSURING THE GNSS ONBOARD INTEGRITY FUNCTION UNDER ADVERSE CONDITIONS: FEASIBILITY AND FLIGHT TEST RESULTS

Butzmuehlen, Carsten, Technische Univ., Germany; Dec. 1997; 10p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

With an increasing system and technology performance of satellite navigation components, the Global Navigation Satellite Systems (GNSS) conquer more and more fields of military and civil applications. Due to the undisputed high level of accuracy and its marginal needs of terrestrial infrastructure, satellite navigation is in principle the most suitable candidate for positioning tasks under adverse environments where conventional radio navigation aids fail. Considering this background, the Institute of Flight Guidance and Control participated recently in a flight test program in Lugano, Switzerland supported by the Swiss Federal Office of Aviation (FOCA). Flight tests were performed under highly dynamic and adverse conditions with the additional use of low-cost inertial information. The landscape in which these tests were realized leads to the risk of extensive shadowing of the space vehicles, thus increasing the probability that the GNSS is not available in order to compute a position solution. Additionally, the mountains provide a reflecting surface of the radio frequency signals. Hence, the possibility of multipath reception is given here as well. This paper deals with the current means that are used to achieve the accuracy and the integrity that is necessary for high-precision and safety-critical procedures. The methods are discussed briefly and flight test results are presented.

PERFORMANCE AND GUIDANCE SYSTEM TESTING USING DIFFERENTIAL GPS ON A FALCON 20 AIRCRAFT

Croll, John B., National Research Council of Canada, Canada; Advances in Flight Testing; Dec. 1997; 8p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Using a Falcon 20 research aircraft, a program was conducted at the Canadian National Research Council (CNRC) to investigate the use of a differential Global Positioning System (GPS) to: (1) provide aircraft guidance on precision instrument approaches, and (2) measure aircraft performance parameters during typical flight test manoeuvres needed for aircraft certification. The initial series of tests used a differential GPS with NovAtel 95 IR receivers installed in the aircraft and at the ground station, and with a VHF radio link to provide real-time differential corrections. This system fell slightly short of the vertical accuracy criteria needed for precision approaches to Category I limits, and did not meet the accuracy criteria desired for flight test measurement. Following an upgrade to a NovAtel RT-20 (trademark) differential GPS, a program was conducted to determine the landing performance of the Falcon 20 on winter contaminated runways (covered with ice or snow). The real-time position and height accuracies of the upgraded system were determined to be less than 20 centimeters, falling well within the accuracy criteria for Category I approaches, and enabling this system to be used as the primary device for measuring aircraft landing distances from a height of 50 feet (15 meters) to a complete stop. During this program, a strong correlation was found between aircraft deceleration during full braking and the runway friction index reported by a ground test vehicle, allowing the aircraft landing distance to be accurately predicted as a function of the runway friction index.

PRECISION NAVIGATION AND SYNTHETIC VISION FOR POOR VISIBILITY GUIDANCE

Sachs, G., Technische Univ., Germany; Dobler, K., Technische Univ., Germany; Schaenzer, G., Technische Univ., Germany; Dieroff, M., Technische Univ., Germany; Dec. 1997; 12p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Computer generated synthetic vision is considered as a means for providing guidance in poor visibility conditions. The synthetic vision comprises as basic elements a 3-dimensional image of the outside world and integrated guidance information like a tunnel display. A precision navigation system is applied which couples differential satellite and inertial sensor data to achieve the required high performance. A flight test program was conceived to cover a wide range of synthetic vision guidance applications (precision approach and landing, low level flight in narrow river valley, curved/steep/short approaches and terrain following in mountainous areas). Four test series at different areas were conducted. The results of the flight test program show that the synthetic vision enables the pilot to precisely control the aircraft. He successfully performed the flight tasks.

VALIDATION OF THE SIMULTANEOUS CALIBRATION OF AIRCRAFT POSITION ERROR AND AIRFLOW ANGLES USING A DIFFERENTIAL GPS TECHNIQUE ON A HELICOPTER

Hui, Kenneth, National Research Council of Canada, Canada; Baillie, Stewart, National Research Council of Canada, Canada; Dec. 1997; 8p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper describes the validation of a technique for the simultaneous determination of pitot-static position error and the calibration curves for angle of attack and sideslip sensors. The Simultaneous Calibration of AirData system (SCADS) technique involves flying the aircraft in a 'wind box' pattern while recording a suite of standard flight test parameters and Differential Global Positioning System (DGPS)

measurements. This simultaneous calibration technique combines the calibration procedure for both position error and airflow angle calibration, and eliminates the need for flying close to the ground during the tests. During the development of this technique using the NRC Falcon 20 aircraft, the results demonstrated that accurate calibrations could be obtained with reduced flight time and cost over conventional calibration techniques. The present paper describes the application of the SCADS technique to the NRC Bell 206B helicopter. The calibration results are presented and are compared with data from other standard calibration methods and verified with manoeuvres not used in the model development. The results from using the SCADS technique have demonstrated better efficiency and accuracy.

AIR TRAFFIC MANAGEMENT: SUPPORT FOR DECISION MAKING OPTIMISATION - AUTOMATION LA GESTION DU TRAFFIC AERIEN AIDE A LA DECISION OPTIMISATION - AUTOMATION

Benoit, Andre, Editor, European Organization for the Safety of Air Navigation, Belgium; Air Traffic Management: Support for Decision Making Optimization - Automation; Dec. 1997; 284p; In English; The Mission Systems Panel Workshop on ATM, 27-29 May 1997, Budapest, Hungary; See also 19980201658 through 19980201677 Report No(s): AGARD-R-825; ISBN 92-836-1064-4; Copyright Waived; Avail: CASI; A13, Hardcopy; A03, Microfiche

As a contribution to the increasing cooperation between NATO and former Warsaw Pact countries, the Mission Systems Panel of AGARD organized a Workshop on Air Traffic Management, held in Budapest, Hungary on 27-29 May 1997. Emphasis was placed on the fundamentals of air traffic handling and an effort was made to establish a fruitful dialogue between experienced experts and young mathematicians, physicists and engineers, offering a fresh approach to the on-line conduct of traffic management. The main characteristics of Air Traffic Handling were outlined; it is a large-scale, international, multi-disciplinary and complex system. The aircraft, the basic element of air traffic, was given considerable consideration: the manner in which it is flown and its dynamics, the potential role of the on-board flight management system, the current and expected level of automation, and the advent of unmanned military aircraft. Could Air Traffic Handling become a discipline in itself as part of the academic subject of aerospace? What assistance could be made available to the human controller in the present types of operation? Finally, if it was intended to make major improvements to the management of all flights, what optimization techniques were suitable for on-line operations? These important questions were debated in a session devoted to the fundamentals of air traffic management. An attempt was then made to illustrate some trends in the optimization and automation processes: arrivals management in the PHARE programme; application of genetic algorithms to mid-air collision avoidance; the detection and resolution of conflicts using coupled force field techniques and a broad look at global traffic optimization. Plans and perspectives were presented: human-machine interface in the Hungarian MATIAS project; a US view of the situation as seen by the FAA; the CNS/ATM concept as an ICAO prospective and the EATCHIP-EATMS concept offered as a European perspective. The Round Table which ended the meeting offered strong encouragement to the academic and scientific communities to inform their members of the nature, complexity and interest of the problems - numerous and varied - raised by the need to improve the presently critical air traffic situation. Examples of outstanding doctoral dissertations were included in this Workshop programme.

In a recent presentation, Dominique Colin de Verdiere considered which areas of air traffic handling need to be optimized. The question is not only pertinent, but must be answered if we are to meet with the intention of turning our attention to the same areas. Several optimization and automation aspects will be discussed in the course of this workshop. In this general introduction, the intention is simply to outline some essential and basic problems concerning the conduct of air traffic.

Air Traffic Management is a very complex and challenging domain. To cope with future traffic demand, while still maintaining or even increasing safety and efficiency of air traffic operations, intelligent machine functions have to be developed to assist the human operators in their mental control tasks. The specific requirements of the ATM domain necessitate sophisticated and well-designed assistance tools. Their most significant characteristics, design principles and structures are discussed and exemplified in a real-world application.

European centralized air traffic flow management (ATFM) is still in its early stages of development and has urgent and extensive needs in terms of decision support tools. This paper provides a brief overview of research in ATFM and discusses the feasibility of optimization approaches to European ATFM. Three optimization models for re-routing air traffic flows and their test results are presented and analyzed.

FLIGHT MANAGEMENT SYSTEMS IN THE NEW AIR TRAFFIC MANAGEMENT (ATM) ENVIRONMENT

Meredith, J. F., Smiths Industries Aerospace and Defence Systems Ltd., UK; Air Traffic Management: Support for Decision Making Optimization - Automation; Dec. 1997; 10p; In English; See also 19980201657; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The new ATM environment will place additional requirements on Flight Management Systems. It will be necessary to provide data on position and aircraft trajectory to be used by other aircraft and by ground based air traffic managers, at a level of availability and integrity which is consistent with the safety of the air traffic system. Corresponding data from the other aircraft in the airspace must be analyzed in order to identify potential conflicts. The algorithms for the resolution of potential conflict with other aircraft must be based on a common strategy which applies throughout all aircraft. The way in which such conflict resolution could interface with the FMS flight plan and with optimization are discussed.

ATM AS PART OF THE AEROSPACE ENGINEERING CURRICULUM

Simpson, Robert W., Massachusetts Inst. of Tech., USA; Dec. 1997; 4p; In English; See also 19980201657; Copyright Waived; Avail: CASI; A01, Hardcopy; A03, Microfiche

The problems of changing the traditional aerospace engineering curriculum to provide an education for young engineers interested in developing the new forms of ATM (air traffic management) systems is discussed. The new ATM systems will introduce quite different concepts for operational procedures and a much higher level of traffic handling performance using new technologies for communications, navigation, and surveillance identified by the FANS Committee of ICAO, and will introduce digital datalink and automated decision support processes in the cockpit and at the AT controller's console. It is concluded that subjects in human factors and operations research pertinent to ATM operations are badly needed, and that there is not enough time in the normal curriculum to teach all necessary subjects for a completely qualified ATM project engineer so that short courses are needed for engineers from industry to prepare them for this responsibility.

The ever increasing demand for air traffic is silting up the Air Traffic control system. As a response, the high level management moves towards a business approach: increase system capacity to meet the demand, monitor the quality of the product, in particular safety, and reduce the cost. Air Traffic Control is a complex task that involves human controllers and machines. Today, there is a consensus such that, at least in the enroute environment, the human controller is a major bottle-neck. Accordingly, the introduction of a higher level of automation is considered to be the way forward. The EATCHIP

program of Eurocontrol, in close cooperation with its member states is defining the EATCHIP Phase III ATC system generation that aims to improve ATC capacity and flight economy whilst at least maintaining the present safety level. It intends to achieve this by introducing automation in a human-centered approach. The paper describes some human characteristics related to the introduction of automation in general, current trends in future system automation and associated safety risks. The paper concludes with a proposal for a pragmatic way ahead including how to gain controller acceptance.

In the frame of this workshop dedicated to support for decision making optimization and automation, it appeared useful to the organizing team to include a general presentation of what optimization means and of the various existing methods to solve optimization problems. In this paper we will try to classify the optimization techniques according to the type of problems they are intended to solve and to the type of solutions that may be expected for each of them. We do not try to solve exhaustively as we are more concerned with the general methodologies. In fact many methods exist. For all types of methods, adaptations and improvements have been developed in order to increase their efficiency, their rate of convergence or decrease computing time. For specific applications, the best results are often obtained from the combination of several algorithms. In taking advantage of the specificity of each, efficient methods are then obtained.

PHARE DEMONSTRATION: ARRIVALS MANAGEMENT

Reichmuth, Johannes, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Dec. 1997; 12p; In English; See also 19980201657; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper reports first results obtained from the real-time simulations in the frame of the second PHARE Demonstration (PD/2) performed during December 1996 to February 1997 at DLR in Brunswick. The experimental set-up of three different configurations for the management of arrivals in an extended TMA airspace using the Tools developed within the PHARE program in connection with DLRs Air Traffic Management and Operations Simulator (ATMOS) is described. A conventional arrival management system is compared with advanced arrival management based on time accurate trajectory predictions provided from ground as well as from the air. An overview on the advanced Ground Human Machine Interface developed for these experiments is given. Eight controller teams from seven European countries take part on the experiment. The first analysis of the collected data in terms of performance, workload and acceptance supports the ideas of the presented operational concepts for the Approach problem further to be included within future Air Traffic Management Systems.

Automatic control has been a subject of studies for the last twenty years. It involves many difficult problems that have to be solved:

conflict detection, modelling of uncertainties on trajectories, clustering of 1-to-1 conflict to find unconnected n-aircraft problems, etc... Moreover, the n-aircraft conflict resolution problem is highly combinatorial and cannot be optimally solved using classical mathematical optimization techniques. The set of admissible solutions is made of many unconnected subsets enclosing different local optima, but the subset enclosing the optimum cannot be found a priori. In this paper, we present an automatic conflict solver and its implementation in an air traffic simulator, with statistical results on real traffic over France. This solver, which takes into account speed uncertainties and allows aircraft to fly on direct routes, solves every conflict on a loaded day, and gives each aircraft its requested flight level and departure time.

The paper describes concepts that relate to Global Air Traffic Management (GATM) emphasizing the potential of mathematical modeling and behavioral simulation in creating a flexible and efficient traffic management system. These concepts include design methodology, flow management, airspace structure and optimal runway scheduling. They reflect the author's theoretical study and experience on the subject of Air Traffic Control, combining knowledge and ideas from related large scale optimal dynamic resource allocation problems encountered in military logistics, transportation and economics. The resource in question is the airspace-time and the paper discusses alternative ways, such as the space-time market, for sharing it in a safe, expedient and cost effective way. The paper concludes with optimal runway capacity results for the two major airports of Frankfurt and Chicago O'Hare.

OPTIMAL SCHEDULING WITH MAXIMUM POSITION SHIFT (MPS)
CONSTRAINTS: A RUNWAY SCHEDULING APPLICATION**

Trivizas, Dionysios A., Global Air Traffic Management, Greece; Dec. 1997; 10p; In English; See also 19980201657; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The airport's runway system may be viewed as a queueing system where a stream of flights is waiting to receive take-off or landing "service". It has been observed that changing the order of runway operations results in a different runway throughput or "capacity". This is due to wake vortex considerations, whereby the minimum horizontal separations between successive landing aircraft depends on their weight and final approach speed. This observation gave rise to the Optimal Runway Scheduling Problem (RSP) that seeks to find the optimal rearrangement of flights that would maximize runway throughput. RSP is complicated by the fact that in a real time system, where flights appear randomly over time, there is always a possibility of some flight being indefinitely displaced backwards in the queue. This calls for the Maximum Position Shift (MPS) constraints which assure that no flight will be displaced in the queue by more than a pre-specified number k of positions. The term queue refers to the ordering of flights according to the First Come First Served (FCFS) discipline. The RSP is typical of queueing systems when service rate depends on customer ordering. It is also a variation of the notorious Traveling Salesman Problem (TSP). The paper presents the Parallel Dynamic Programming RSP algorithm, developed in Trivizas' doctoral dissertation. Timely solution is crucial to real time dynamic scheduling, and so the paper concentrates on its computational aspects. It is shown that the MPS constraints reduce the size of the problem's solution space, interpreted as a computational neighborhood around the FCFS sequence of "radius" equal to the MPS value. This neighborhood has the form of a permutation tree (PT). It is shown here that traversing the PT using a Branch and Bound (BB) Depth First Search, a brute force method, may require an amount of time which is expo-

nential in the number n of customers (flights). It is further shown that the search may be organized efficiently using Breadth First Search Dynamic Programming which exploits the de-coupled, stage invariant solution space structure, whose size, $2(\exp \text{MPS})^n$, is linear in n and exponential only in the bounded value of MPS. Stage invariance and label vector coding of the solution space allow for a generalized cross-section of the solution space; this leads to the concept of a parallel computation engine that sweeps the solution space in time linear in n .

This paper presents an airborne conflict detection and resolution logic, based on the coupled forces field technique. This technique defines a general framework for decentralized and reactive coordination for mobile agents. An experiment has been carried out to evaluate this approach. The background, role of controllers and pilots, and what type of principles and the application of the technique to air traffic, as well as the principal results are presented.

The Hungarian Air Traffic and Airport Administration is to replace the current Budapest Area Control Centre (ACC) with a new, purpose-built building at Ferihegy. The new ACC system is planned to be fully stripless and will include area control, terminal area control, aerodrome control, military control and flight information sectors. Readers involved in air traffic control may find it interesting how the system is planned to fulfill the controllers' requirements. The article contains the description of those functions, which are planned to be used by the operational staff in the OPS Room, so the technical and maintenance windows are omitted. The windows of the radio and telephone systems are also omitted.

PLANS AND PERSPECTIVES FOR RESEARCH AND DEVELOPMENT IN AIR TRAFFIC MANAGEMENT**

Miller, Clyde A., Federal Aviation Administration, USA; Dec. 1997; 16p; In English; See also 19980201657; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

In 1993, the U.S. Congress passed the Government Performance and Results Act (GPRA). The purpose of the legislation is to improve Federal program effectiveness and public accountability by promoting a focus on results, service quality and customer satisfaction. The GPRA shifts the focus of program accountability from agency internal activities to the products and services planned to be placed in the hands of external customers and the eventual benefits to be achieved as a result. Decisions regarding expenditures of public funds will be justified in terms of these products, services and benefits. This perspective is very useful in planning and prioritizing research and development (R&D) projects in air traffic management (ATM). In particular, it would be useful to establish a comprehensive framework

of performance goals to guide R&D investments in ATM. Some progress toward this end has been achieved at the Federal Aviation Administration (FAA).

CNS/ATM CONCEPT: ICAO PROSPECTIVE

Dedryvere, A., Direction de la Navigation Aérienne, France; Carel, O., Direction de la Navigation Aérienne, France; Dec. 1997; 16p; In English; See also 19980201657; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

In 1983, ICAO founded the FANS Committee (Future Air Navigation System) to trigger a global reflection on the radioelectric means to be used by Civil Aviation in 2000 and further. In dense areas (like the European core area between London, Paris, Milan, Berlin and Amsterdam) the growth of traffic will no more be manageable by the current control methods, i.e. multiplying the number of sectors more and more. En-route and airport delays generate time and financial losses. In oceanic and desertic areas the traffic is low and will remain low for a long time. The lack of communication and navigation means generates large lateral and longitudinal separations which sometimes do not avoid near misses over continental crosspoints. There was a need for more reliable but affordable controller-to-controller and controller-to-pilot links associated with modern and reliable navigation aids. Aviation is generally famous for technical modernity but the International Maritime Organization was the first to implement a satellite communication system designed between 1976 and 1979 and put into operation on 01/02/1982. It was then possible for maritime crew and travelers to phone everywhere in the world, when aircraft pilots were unable to have a comfortable contact with ATC.

Some ideas about what may be coming next in European Air Traffic Management (ATM) are presented. More specifically, the following items will be discussed: (1) Why is there a need to act at all; (2) An attempt to explain existing plans in Europe to address challenges; and (3) to show that we have at least some idea of how to address those challenges, by presenting some results, which will lead us to a possible path forward, and finally to conclusions.

A KF-BASED INTEGRATION SYSTEM FOR LAND VEHICLE TRACKING FROM REAL DGPS AND INS DATA

Regazzoni, Carlo S., Genoa Univ., Italy; Teschioni, Andrea, Genoa Univ., Italy; Tacconi, Giorgio, Genoa Univ., Italy; Apr. 1998; 12p; In English; See also 19980210650; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The present work is addressed to perform an estimation in an accurate and robust way of the trajectory of a land vehicle by using a Differential Global Positioning System (DGPS) and an Inertial System (INS). The use of a Kalman Filter (KF) approach for integration, data-fusion and estimation tasks has been proved as able to providing precise and robust evaluation of cinematic variables (linear position and velocity) even in the case of long missions or under critical conditions of temporary incompleteness or unreliability of part of the acquired data. From the state of the art, it can be seen that the DGPS is very precise sensor providing 3D geographic position, but present low output rate and temporary signal loss or accuracy degradation, while the INS provides continuous outputs of rotation angles and linear acceleration with high output rate but the inertial units have burdensome intrinsic errors which bring about a degradation of precision

increasing with time. Practically, the integration of DGPS and INS is forecast to provide continuous estimates over time, corrupted by small and almost unchanging errors. The system has been tested over an extensive set of real data providing good results both in precision and in robustness.

RELIABLE AUTONOMOUS PRECISE INTEGRATED NAVIGATION RAPIN FOR PRESENT AND FUTURE AIR-VEHICLES

Koehler, Thomas, Daimler-Benz Aerospace A.G., Germany; Tumbraegel, Franz, Daimler-Benz Aerospace A.G., Germany; Beyer, Juergen, Honeywell Regelsysteme G.m.b.H., Germany; Jul. 1998; 16p; In English; See also 19990007836; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The operation of unmanned vehicles ranging from strategic missions of autonomous high altitude reconnaissance to tactical missions of reconnaissance and strike/attack impose new requirements to the guidance systems in the area of reliability and safety. This includes all phases of the mission start, cruise, attack/strike and 'Low Level' operation including precision approaches even under bad weather conditions and in a hostile environment. A reliable, continuous and precise navigation system is of paramount importance for the guidance function even more for unmanned air vehicles. The Project RAPIN, the name standing for 'Reliable Autonomous Precise Integrated Navigation', combines the navigational research activities at Daimler-Benz Aerospace AG (Dasa) Military Aircraft teamed with Honeywell Regelsysteme GmbH in that context. RAPIN integrates 'Laser Inertial Navigation System' (LINS), P(Y) code 'Global Positioning System' (GPS) and 'Terrain Referenced Navigation' system (TRN). The data fusion concept is to combine all available information in one MAIN filter gaining the highest accuracy. In order to provide uncontaminated backup solutions in case of sensor failures, a bank of SUB filters is working in parallel. Each SUB filter uses a different subset of sensor signals. It is the objective of this paper to report on the system concept, the design of the prototype, and to describe the realization process. Subsequently, the paper will present first and preliminary results including flight trials on C-160 Transall ANA/FRA (Autonome Navigationsanlage/Flugregelungsanlage) performed by the "Wehrtechnische Dienststelle 61". The possible application of this generic system varies from uninhabited reconnaissance / fighter aircraft over transport aircraft to rescue helicopters.

A machine perception system for aircraft and helicopters using multiple sensor data for state estimation is presented. by combining conventional aircraft sensors like gyros, accelerometers, artificial horizon, aerodynamic measuring devices and GPS with vision data taken by conventional CCD-cameras mounted on a pan and tilt platform, the position of the craft can be determined as well as the relative position to runways and natural landmarks. The vision data of natural landmarks are used to improve position estimates during autonomous missions. A built-in landmark management module decides which landmark should be focused on by the vision system, depending on the distance to the landmark and the aspect conditions. More complex landmarks like runways are modeled with different levels of detail that are activated dependent on range. A supervisor process compares vision data and GPS data to detect mis-tracking of the vision system e.g. due to poor visibility and tries to reinitialize the vision system or to set focus on another landmark available. During landing approach

obstacles like trucks and airplanes can be detected on the runway. The system has been tested in real-time within a hardware-in-the-loop simulation. Simulated aircraft measurements corrupted by noise and other characteristic sensor errors have been fed into the machine perception system; the image processing module for relative state estimation was driven by computer generated imagery. Results from real-time simulation runs are given.

LOW COST INERTIAL SYSTEMS

Cunningham, T., Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 62-63; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

The advent of the Global Positioning System (GPS) has changed the rules for inertial navigation to a significant degree. By the year 2020 the role of inertial sensors will be as aiding and backup to satellite navigation derived data. Traditional inertial instruments error budgets will, in many instances, be relaxed by at least two orders of magnitude in non-jamming environments. The commercial market, driven by requirements in the automotive electronics area, is expected to provide both accelerometers and gyros at very low cost. Many promising concepts are emerging for low cost inertial components and systems, with accuracy sufficient for a broad spectrum of military applications. These include innovative approaches such as silicon-based Microelectromechanical Systems (MEMS) technology.

HIGH INTEGRITY GLOBAL PRECISION POSITIONING

Schmidt, G., Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 64-65; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

The accuracy of satellite-based global precision positioning systems is primarily a function of the errors in the space and control segment of the system and in user equipment receiver implementation. The integrity (or reliability) of the system is also dependent on the space and control segment, on the receiver user equipment implementation, and dependent on interference (intentional or otherwise) to the broadcast signals. By the year 2020, it is expected that sub-meter accuracies will be obtainable thus allowing navigation and guidance of vehicles with very high 3 dimensional accuracy, including the vertical dimension. In addition to the high level of position accuracy provided by satellite navigation, extremely high levels of velocity and time accuracy will be achieved through closely-coupled integration with inertial sensors. However, jamming and intentional interference are expected to remain a serious issue for military operations, as well as civilian use, in spite of great improvements in satellite navigation receiver anti-jamming capability.

The AGARD Structures and Materials Panel held a specialists' Meeting to address composite repair of military aircraft. The meeting focused on two main areas, repair of metal structures using composite patches and repair of composite structures using composite or metal patches. The work presented had direct application to the maintenance and support of military aircraft. Repair of military aircraft provides both a means to extend the useful life of the airframe beyond the original design life and a method to maintain military readiness by returning damaged aircraft to service.

BONDED COMPOSITE REPAIR OF METALLIC AIRCRAFT COMPONENTS: OVERVIEW OF AUSTRALIAN ACTIVITIES

Baker, A. A., Defence Science and Technology Organisation, Australia; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 14 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

After first providing an overview of the status of Australian applications of bonded composite repairs to metallic aircraft structure (mainly based on boron/epoxy composites) the problems in certifying composite repairs to critical cracks in primary metallic structure are discussed. The development of acceptable generic certification procedures is essential if the use of this efficient cost-effective repair technology is to be widely employed in military and civil aircraft. One requirement for certification is the ability to predict the fatigue-crack growth behavior in patched components. An approach to developing this capability is described, based on Rose's model to estimate stress intensity in patched panels. The model is extended to allow for disbonding damage in the patch system. Experimental results are presented to demonstrate the validity of this approach for boron/epoxy-FM73 repairs to aluminum alloy 2024T3.

STATUS OF BONDED BORON/EPOXY DOUBLERS FOR MILITARY AND COMMERCIAL AIRCRAFT STRUCTURES

Belason, E. B., Textron Specialty Materials, USA; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 12 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Bonded boron/epoxy doublers are an alternative method vs. riveted doublers for repair and reinforcement of metallic aircraft structures. The boron/epoxy doublers provide cost and/or performance advantages for many applications. Today over 4,500 are flying on military aircraft, mostly in Australia and the U.S.A., and the use is increasing. Commercial aircraft, which are also aging, are beginning to use this technology, with about 50 boron doublers flying for flight evaluation since 1989 (plus about another 100 since the mid 1970s in France). This paper summarizes the major uses of boron/epoxy doublers, focusing on recent and current U.S. applications (other papers at this Meeting describe activities in Australia, Canada, and France). These include a 1993 report summarizing the successful use on the wing pivot of over 400 F-111s for 20 years (no disbands have been noted); fleetwide installations on the B-1 and C-141 (over 1800 doublers); and flight testing on F-16, T-38, C-130 and KC-135 aircraft. Commercially there have been successful flight evaluations on 2 Fed Ex 747s and the Lycoming ALF 502 engine cowl on 2 BAE 146s. A Service Bulletin has been issued for retrofit of over 1200 cowl for the latter. This paper also summarizes the installation process (which is very viable), and describes two recent technical advances in chemically preparing aluminum surfaces for bonding of boron/epoxy doublers. This paper also presents the results of an extensive test

program sponsored by Textron at Boeing of 110 ultimate tensile strength and 143 fatigue tests of boron/epoxy doublers bonded to 7075-T6 aluminum with simulated cracks.

ADHESIVELY BONDED COMPOSITE PATCH REPAIR OF CRACKED ALUMINUM ALLOY STRUCTURES

Poole, P., Defence Research Agency, UK; Young, A., Defence Research Agency, UK; Ball, A. S., British Aerospace Defence Ltd., UK; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 12 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Research at the Defence Research Agency (DRA) on adhesively bonded composite patch repair of fatigue cracked aluminum alloy structures is reviewed briefly. Theoretical and experimental results are reported which indicate the effectiveness of such repairs in terms of the reductions in stress intensity factor due to patching. The influence of warm-moist environments on the long-term performance of bonded patches is considered, and the advantages and disadvantages of using carbon fiber reinforced plastic (CFRP) patches, rather than boron fiber reinforced plastic (BFRP) patches, are discussed. An investigation by British Aerospace of the feasibility of using bonded composite patches to repair cracked primary aircraft structures is summarized. For the range of applications investigated, bonded composite patch repairs are shown to offer potential savings of 60-75 percent, compared to conventional repair methods. The current position regarding in-service trials is summarized, with no evidence of crack growth after 990 flying hours.

During the 70's, the availability of unidirectional boron fiber fabric at Dassault Aviation did allow reinforcement of metallic structures by direct ply lay up on the metal. To be able to apply these reinforcement on airplanes, it was necessary to define a resin system inducing low thermal stresses in the metal during its cure, and with acceptable mechanical properties after aging. Validation was done by simple tests on samples, by complex test with simultaneous thermal and mechanical cycling, and application of test repairs on the major fatigue test of the Mercure airplane. Reinforcements of that type are in service for almost 20 years on the Mercure airliner.

An investigation into the effectiveness of bonded boron/epoxy composite patch repairs on edge notched Al 2024-T3 sheets has been completed. Testing was carried out under variable amplitude load and

temperature cycling. Nine sandwich type specimens were precracked of which eight were repaired using bonded precured unidirectional boron fiber reinforced epoxy patches. Three structural adhesive systems were evaluated, two thermally activated epoxies, FM73 and FM300, and a room temperature cure acrylic, Versilok 201. The variable amplitude load sequence used was FALSTAFF, a typical fighter aircraft loading spectrum. The temperature profile was derived from F/A-18 usage data. Temperatures varied between -35 C and +80 C with a one in eight temperature cycle occurrence of +108 C. The effect of moisture absorption in the adhesive and the matrix was also investigated. Bonded patches on three specimens were preconditioned to a moisture weight gain of 1.5 percent prior to testing. The data generated compares specimen fatigue crack growth rates between the three adhesives for three environments: room temperature, temperature cycled and temperature cycled with moisture preconditioning.

DESIGN AND STRUCTURAL VALIDATION OF CF116 UPPER WING SKIN BORON DOUBLER

Smith, J., Bombardier, Canada; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 11 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Cracks were found around fastener holes in the critical area known as the 'Golden Triangle' on the upper wing skin of several CF116 aircraft. To restore the structural integrity of the wing, cracks around these fastener holes are removed and interference fit steel bushings are installed. A boron-epoxy doubler is then bonded over the reworked area to reduce stress levels. The doubler is viewed as a fatigue enhancement device and not as a repair to a cracked skin. An analytical methodology is used to assess the bond line integrity and the load transfer in the doubler. A 49% reduction of stress level is predicted by the bonded joint analytical approach. A finite element analysis reveals that a 47% stress reduction is expected in the exterior surface of the wing skin, while a 37% reduction in the interior surface is predicted. Based on a strain survey performed following the installation of a doubler on the CF116 full scale fatigue test, it is shown that analytical predictions agree with experimental results.

A FEAM BASED METHODOLOGY FOR ANALYZING COMPOSITE PATCH REPAIRS OF METALLIC STRUCTURES

Pipkins, D. S., Georgia Inst. of Tech., USA; Atluri, S. N., Georgia Inst. of Tech., USA; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 16 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

A Finite Element Alternating Method based methodology applicable to the analysis of composite patch repairs of metallic structures is presented. The method is completely general and may be used to efficiently analyze factors affecting repair design such as: global stiffening of the aircraft structure due to the high stiffness of the composite patch; the effect of size, shape, thickness and material properties of the composite patch on the crack-tip stress intensity factors; the effect of the material properties of the adhesive on the crack-tip stress intensity factors; the effect of thermal cycling on the composite repair; and the effect of disbands on the effectiveness of the composite repair.

Lockheed Aeronautical Systems Company (LASC) -- in a program sponsored by the USA Air Force, Warner Robins Air Logistics Center, C-130 Directorate -- has developed concepts wherein bonded high-modulus composite materials can be applied to structurally repair or enhance the wing box of C-130 aircraft. Two separate approaches are taken. In the first, boron/epoxy reinforcing strips are applied to wing box lower surface structure to relieve high stress at a particular location in the wing surface panel. This modification is ideally used on undamaged structure to prevent wing surface cracking. In the second approach, graphite reinforced patches are applied in the same vicinity to arrest crack growth. Both concepts were successfully demonstrated on opposite sides of a full-scale wing test article. Design details, the materials and processes, the methods of installation and the measured effectiveness of both the boron/epoxy strips and the graphite/epoxy patches are discussed.

EVALUATION OF PATCH EFFECTIVENESS IN REPAIRING AIRCRAFT COMPONENTS

Sih, G. C., Lehigh Univ., USA; Gdoutos, E. E., Thrace Univ., Greece; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 8 p; In English; See also 19950021083; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Reinforcement of aircraft components by patching is never completely effective because of improper bonding or damage of the reinforcement in service. There is always the uncertainty for evaluating the remaining strength or life of a repaired structure. Developed in this work is a methodology for evaluating the reinforcement effectiveness by considering two basic types of partially damaged patches; they are referred to as collinear and transverse debonding with respect to the crack plane. The former refers to debonding over a region ahead of only one of the crack tips where the load and geometry are symmetric across the crack plane, while the latter is concerned with debonding over a region to the side of the crack where symmetry is no longer preserved across the crack plane. Finite elements are employed to obtain the stresses and strains from which the strain energy densities can be determined for analyzing the failure behavior of the patched panels. The local and global maximum of the minimum strain energy density function, designated by $((dW/dV)_{sup max, sub min})_{sub L}$ at L and $((dW/dV)_{sup max, sub min})_{sub G}$ at G, are found and applied to define failure instability. The distance ell between L and G serves as a measure of crack instability; it increases with the debonded area. That is, debonding tends to enhance failure instability by fracture initiating from the existing crack. For approximately the same area of debonding, crack initiation for collinear debonding would be more unstable as compared with transverse debonding for loads directed normal to the crack. Introduced also is a Patch Effectiveness Index (PEI) that serves as a measure of the load carrying capacity of the damaged patch. In this case, transverse debonding is more detrimental than collinear debonding because a more significant reduction in the load transfer path occurs in the former case. In general, both ell and PEI would have to be considered for assessing the integrity of the damaged patch.

The Navy is unique in that a portion of the maintenance actions performed on operational aircraft must be accomplished on board ship

or in remote field locations. Historically, Navy driven composite repair programs have addressed materials and concepts specifically directed at accomplishing repairs in the fleet operating environment. This paper discusses recent developments in the area of composite repair materials for the application of bonded patches to honeycomb and complex shaped monolithic composite structure. A two part adhesive that meets the storage and processing requirements for field repair applications was evaluated for use in repair of honeycomb structure. Low temperature adhesive processing and honeycomb compatibility tests were investigated. In another effort, wet lay-up repair resins and processes were characterized for repair of highly curved composite structure. The materials and equipment used in the study are fully compatible with field repair requirements. Composite repair materials for application of bonded patches to honeycomb and complex shaped monolithic composite structure are described. Low temperature adhesive processing development for bonding composite patches to moisturized structure is described. Cure temperatures as low as 90 C were used for curing a two part ambient storable adhesive. Mechanical properties and thermal stability of the cured adhesive is reported using a number of cycles. In another effort wet lay-up repair resins and processes were characterized which allow for the fabrication of fully inspectable wet lay-up patches. The materials and equipment are fully compatible with field repair requirements. Laminate mechanical properties and resin storage stability were characterized and reported.

ON AIRCRAFT REPAIR VERIFICATION OF A FIGHTER A/C INTEGRALLY STIFFENED FUSELAGE SKIN

Bauer, J., Deutsche Aerospace A.G., Germany; Maier, A., Deutsche Aerospace A.G., Germany; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 14 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

A considerably large four point bending test box was available simulating the curved integrally stiffened CFC fuselage skin of a fighter aircraft. This box was used for a skin repair trial with subsequent testing. The repair was performed in the environment of an external test laboratory, i.e. abroad of the original shop or maintenance facilities. 'On Aircraft' conditions have been simulated with all the referring access, tooling and quality assurance difficulties. The repaired test box demonstrated during static testing, loading the repair in tension, compression and shear, that the applied repair procedure is feasible to be applied on CFC structures. The repair procedure and the subsequent testing will be presented and the results will be discussed.

RAPID REPAIR OF LARGE AREA DAMAGE TO CONTOURED AIRCRAFT STRUCTURES

Frailey, James A., Lockheed-Fort Worth Co., USA; Carter, Douglas W., Wright Lab., USA; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 9 p; In English; See also 19950021083; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

In a program sponsored by Air Force Wright Laboratory (WL/FIVST), Lockheed Fort Worth Company has developed field-level procedures for repair of large area damage to highly contoured aircraft structures. The combination of aircraft structures designed with enhanced survivability and the utilization of larger and more powerful ballistic threats have resulted in the requirement to develop new, creative approaches for rapid repair of large area structural damage. Furthermore, current aircraft design employing advanced composite materials on highly contoured surfaces increases the challenge of implementing workable battle damage repairs. This paper details the development of an advanced battle damage repair concept designed to repair damage up to approximately 15 inches in diameter on highly contoured surfaces. It employs a quick, reusable tooling mold that replicates the contour of the damaged aircraft for the purpose of processing a composite patch. Several one year room temperature stor-

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

able, thermoset, composite systems were examined for processability, handleability and mechanical performance to determine their suitability as repair patch materials. The most promising were further tested and demonstrated in a large scale validation test.

COMPOSITE REPAIR OF A CF18: VERTICAL STABILIZER LEADING EDGE

Maier, A. E., Deutsche Aerospace A.G., Germany; Guenther, G., Deutsche Aerospace A.G., Germany; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 16 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper describes the engineering and manufacturing procedures that were applied in a repair task of a CF18 Vertical Stabilizer Leading Edge, made out of CFC honeycomb structure with multiple in-service impact damages in an aerodynamic sensitive area of the fin. 'On-aircraft' damage assessment, manufacturing of a relatively thin contoured CFC doubler, replacement of metal honeycomb core and finally quality assurance and strength verification procedures of the repair are described to restore full design strength of the component and the operational aircraft capability.

COMPOSITE REPAIR ISSUES ON THE CF-18 AIRCRAFT

Russell, A. J., Defence Research Establishment Pacific, Canada; Ferguson, J. S., Defence Research Establishment Pacific, Canada; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 8 p; In English; See also 19950021083; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper addresses three separate composite repair issues currently being investigated at the Defence Research Establishment Pacific (DREP) in support of Canada's CF-18 aircraft. First, the problem of skin/core debonding that can occur during elevated temperature bonded repairs of honeycomb sandwich structure is discussed and the results of tests which help to quantify the role played by bondline degradation are presented. Next, the final development phase of an on-going effort to establish a reliable and effective means of repairing delamination damage is reported. In particular, the design of a resin injection device and a series of tests to evaluate its performance are described. Finally, a battle damage repair issue, namely the advantages and disadvantages of cleaning up the damaged composite material found around entry and exit holes created by live fire, is discussed. Test data is presented which compares the different consequences under tensile and compression loading.

REPAIR TECHNOLOGY FOR THERMOPLASTIC AIRCRAFT STRUCTURES

Heimerdinger, M. W., Northrop Grumman Corp., USA; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 12 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The Flight Dynamics and Materials Directorates of the U.S. Air Force Wright Aeronautical Laboratories jointly sponsored a program for 'Repair Technology for Thermoplastic Aircraft Structures' (REPTAS) performed by Northrop Corporation, Aircraft Division. In the program Northrop developed, validated and demonstrated on-aircraft repair design concepts and processes for field repair of advanced thermoplastic structures. The REPTAS program was accomplished through the performance of a 48-month effort comprising three phases. Phase 1 assessed field level repair facilities and technology

that are currently available and identified their applicability to repair thermoplastic (TP) structures. A baseline aircraft structure was selected to validate the selected repair process. Currently available thermoplastic materials were reviewed and materials selected for evaluation. In the selection process the objective was to select one semicrystalline, one amorphous, and one pseudo-thermoplastic material. APC-2 was evaluated as the baseline material for the process development efforts. Novel processing techniques were investigated for the repair procedures. Phase 2 developed the selected technologies for the on-aircraft repair of TP structures at a coupon and subelement level. Design concepts were developed that are compatible with field level capabilities and restore structural integrity to the aircraft. In the process of developing a bonding procedure using polyetheretherketone (PEEK) as the bonding film, it became apparent that the required bonding temperature of 385 C (725 F) created internal thermal stresses in the base structure and resulted in unacceptable delaminations. As an alternative, an investigation of amorphous bonding was included which demonstrated its feasibility for TP repair. In Phase 3 a full-scale advanced thermoplastic composite structural component was selected and used as a demonstration article for the selected design concept.

REPAIR OF HIGH TEMPERATURE COMPOSITE AIRCRAFT STRUCTURE

Connolly, Jerome J., Vought Corp., USA; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 12 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper describes the final portion of a high temperature composite repair development program sponsored by Wright Patterson Materials Directorate. Initially, BMI adhesives and prepreps were selected based on their compatibility with in-service repair cure scenarios. These typically involve curing in a non-autoclave environment using vacuum consolidation only. The selected material systems were then used to develop a comprehensive repair procedure for highly curved aircraft structure. Once developed, the procedure was then applied to a curved structure representative of a flight surface leading edge. Baseline and repair specimens were fabricated and tested in compression at both room temperature dry and elevated temperature dry conditions. The results of these test validated the repair procedure.

EXTERNAL PATCH REPAIR OF CFRP/HONEYCOMB SANDWICH
Wolf, K., Eurocopter Deutschland G.m.b.H., Germany; Schindler, R., Eurocopter Deutschland G.m.b.H., Germany; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 11 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper addresses the repair of impact-damaged honeycomb sandwich structures with thin skins made of carbon fiber reinforced

plastic (CFRP). An experimental study concerned with evaluating several types of bonded external patch repairs is presented. The evaluation included cocured as well as precured patch techniques utilizing advanced repair materials. Three repair schemes were applied to honeycomb sandwich manufactured from 125 C as well as 175 C curing carbon fiber reinforced fabric preregs. The effectiveness of the repairs was examined through a series of static and fatigue compression tests. Based on the mechanical test results and a comparison of the repair procedures it was found that the bonded precured patch concept is the most suitable approach for repairing impact-damaged sandwich structures under field-level maintenance limitations.

Significant damage to graphite/epoxy laminates up to 16 plies in thickness is often repaired with a bonded external patch. This type of repair is well suited to honeycomb panels and is relatively easy to apply even under field conditions. Thicker laminates generally carry too much load for external patch repairs and so either bolted patches or scarf repairs are generally used. Scarf repairs exhibit a nominally uniform shear stress distribution within the joint and have the advantage of low peel stress due to the lack of eccentricity in the load path. Scarf repairs are, however, difficult to produce, may involve the removal of a significant amount of parent material, and the uniform shear stresses may make the joint susceptible to creep failure. An experimental program was undertaken to determine the strain capacity of a scarf repair to a 21 ply laminate. The aim of the program is to demonstrate a strain capability in the repair of at least 5200 micro-strain when tested under hot/wet conditions. Although some of the specimens tested have achieved this strain level, the performance of the current scarf joint is marginal under these conditions. Detailed analysis of this joint shows that high stresses arise from ply drop-offs within the repair doubler and at the ends of the scarf taper. Good correlation has been observed between the results from the Finite-Element models and those from experimental specimens, indicating that the models are a useful tool to assist in the design of joints of this type.

SCARF JOINT TECHNIQUE WITH COCURED AND PRECURED PATCHES FOR COMPOSITE REPAIR

Elaldi, F., Turkish Land Forces Command, Turkey; Lee, S., Institute for Aerospace Research, Canada; Scott, R. F., Institute for Aerospace Research, Canada; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 12 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The scarf joint technique is one of the latest techniques used for repairing composite aircraft structures. This paper describes scarf joints comprised of vacuum and autoclave precured and cocured fiber glass epoxy patches bonded to autoclave and vacuum precured parent fiber glass epoxy laminates. Autoclave and vacuum cured parent laminates and the scarf joints were prepared and exposed to the same temperature and moisture environment for comparison. All specimens were loaded in tension at three temperatures. Interlaminar shear strength (ILSS) tests were also carried out for the parent materials. As expected, the tensile strength and ILSS decrease when the material has been exposed to moisture and tested at elevated temperature. No significant difference was reported for either tensile strength or ILSS between autoclave and vacuum cured materials. The room temperature repair efficiencies are reported for single scarf repairs

comprised of vacuum cocured and precured patches. These repair efficiencies were found to be similar to the efficiency of the autoclave precured patch repair. This result supports the feasibility of scarf joint repairs in base level facilities.

COMPOSITE OR METALLIC BOLTED REPAIRS ON SELF-STIFFENED CARBON WING PANEL OF THE COMMUTER ATR72 DESIGN CRITERIA, ANALYSIS, VERIFICATION BY TEST

Tropis, A., Aerospatiale, France; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 21 p; In English; See also 19950021083; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The introduction into service, in 1989, of ATR72 with an outer wing in carbon led Aerospatiale to develop primary structure repair processes which fulfill Airworthiness requirements and which could be performed by the airlines in typical maintenance conditions. This paper describes the two types of bolted repairs developed within the scope of the wing certification: composite doubler or metallic doubler. An analytical microcomputer calculation program allows the critical area and the strength capability of the repaired panel to be determined. This program is validated by tests.

DAMAGE OCCURRENCE ON COMPOSITES DURING TESTING AND FLEET SERVICE: REPAIR OF AIRBUS AIRCRAFT

Stemmer, G., Deutsche Airbus G.m.b.H., Germany; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 8 p; In English; See also 19950021083; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The application of composite materials to civil aircraft structure was growing during the past 25 years with every new aircraft which went into service. With these materials in commercial use it became necessary to define repairs in the case the component becomes damaged. During fatigue testing at component level the limits for allowable damage and maximum repair sizes were determined for standard damage events and manufacturing defects. The values are depending on structural design, material behavior and local strains or stresses. For simple damages on regular structures necessary repair actions are defined in the Structural Repair Manual. With an approved inspection philosophy the structure is under observation during airline service. It will be presented how the repair philosophy within Airbus Industrie partner companies is defined and which damages were reported on aircraft already in service. Some examples should explain the lessons we have learned from those failures occurred during component testing and airline service.

REPAIRS OF CFC PRIMARY STRUCTURES

Garcianunez, H., Construcciones Aeronauticas S.A., Spain; Barrio-cardaba, A., Construcciones Aeronauticas S.A., Spain; Franganillo, A., Construcciones Aeronauticas S.A., Spain; AGARD, Composite Repair of Military Aircraft Structures; Jan 1, 1995, 10 p; In English; See also 19950021083; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The use of composites in the last decades has been mainly restricted to secondary structures, with repair methods well known to the airlines. In today's aircraft, a significant amount of primary structure is designed and built in high strength composite materials. Repairs for these elements must take into consideration the restoration of structural strength and stiffness, still being easy to be applied by aircraft operators, with a minimum of special facilities, and requiring a minimum of aircraft-on-ground time. A large number of important structural elements in CFC now in service have been designed and

manufactured by CASA. This paper describes how composite repairs are dealt with at CASA, starting from the design board, and the analyses and tests carried out to demonstrate compliance with certification requirements.

The RAAF has used bonded composite patches for structural repairs to aircraft for nearly twenty years, and they are now seen as a reliable alternative to mechanically fastened repairs. To control the implementation of the repair technology, RAAF propose to adopt Engineering Standard C5033 on Composite Materials and Adhesive Bonded Repairs. The Standard addresses repair authorization and design, as well as repair methodology and quality control. This paper will describe the philosophy of repair design contained in the standard, and outline the materials and process controls necessary for performance of repairs which comply with ISO 9001.

RELIABILITY AND MAINTAINABILITY *FIABILITE ET MAINTENABILITE*

Howell, Jan M., Test Wing, 0412th, Edwards AFB, USA; Feb 1, 1995; 63p; In English
Report No(s): AGARD-AG-300-VOL-13; ISBN 92-836-1014-8; Copyright Waived; Avail: CASI; A04, Hardcopy; A01, Microfiche

This AGARDograph outlines the rudiments of reliability and maintainability (R&M) evaluations conducted during initial flight test programs. Many organizations, both military and civilian, prefer to defer R&M evaluations until the new equipment has been delivered to the eventual user. The U.S. Air Force Flight Test Center has long conducted R&M evaluations during initial flight test and has found value in that process. This document discusses, first, the objectives of the early evaluations. Then, the acquisition process and the test planning process, as they relate to R&M evaluations, are presented. The test planning section discusses the data needed for a successful R&M evaluation and the sources of such data. The conduct of the test, analysis of results, and subsequent reporting methods are delineated. Follow-up actions that are needed after the test are considered. In conclusion, the document lists some R&M considerations for the future.

A GENERIC SPECIFICATION FOR SPECIAL PURPOSE AEROMEDICAL EQUIPMENT

Spencer, I., Princess Alexandra Hospital, UK; AGARD, Recent Issues and Advances in Aeromedical Evacuation (MEDEVAC); Feb 1, 1995, 5 p; In English; Copyright; Avail: CASI; A01, Hardcopy; A02, Microfiche

A generic specification for Special Purpose Aeromedical Equipment (SPAME) has been prepared which, if met, would largely overcome the problems faced by medical operators seeking clearance for the use of such equipment in aircraft. It is suggested that this specification might be used by NATO medical forces as a base for future standardization and thus perhaps increased interoperability of aeromedical resources and equipment.

UNIFIED CRITERIA FOR ACT AIRCRAFT LONGITUDINAL DYNAMICS

Hoh, Roger H., Hoh Aeronautics, Inc., USA; Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations; Feb 1, 1995, 9 p; In English; See also 19950024640; Copyright; Avail: CASI; A02, Hardcopy; A02, Microfiche

This paper reports research done by USAF to adequately predict the susceptibility to pilot induced oscillation (PIO) and AGARD's response to the research. It discusses different criteria and characteristics that help to analyze PIO: the concept of phase delay, triggers, the effects of rate limiting, response characteristics and appropriate analysis techniques, and feel system influence. From the evidence presented by USAF, AGARD concludes that there is sufficient evidence that a PIO could be predicted, as could the effects of the bobweight. However, the impact of the actuation behavior may have had a dominant effect on the overall behavior of the aircraft.

FLIGHT EVALUATION OF FOREBODY VORTEX CONTROL IN POST-STALL FLIGHT

Loss of directional stability in a post-stall flight environment has become a major design issue for future fighter aircraft. Numerous studies have addressed this issue, either from an aerodynamics perspective or through use of propulsive forces generated by vectoring exhaust nozzles. The X-29 aircraft, with its forward swept wing and other advanced technologies, suffers loss of directional power above 40 degrees angle of attack (AOA). An exploratory development program was undertaken on this configuration to regain the lost stability through use of a pneumatic system on the aircraft nose which influenced the external flow field, generating significant side forces useful for control. Wind tunnel test results were inserted into the X-29 flight simulator at NASA Dryden Flight Research Facility and the simulator was used to support a critical flight experiment of this technology. This experiment is the subject of this paper.

The RAFALE program was conceived from the beginning to define, develop and produce a general-purpose aircraft meeting the future needs of the State - the Army, Air Force, and Navy. The Navy version is intended to equip the French naval air forces by the end of the decade. It will operate starting from the conventional propulsion Foch and the Charles De Gaulle nuclear aircraft carrier. Furnished with a numerical flight control system, the RAFALE M01 prototype is the first aircraft with delta canards to be catapulted from an aircraft carrier (April 1993). It is also the first naval aircraft to use the original method of catapult-assisted dihedral launching. The study of naval aircraft catapult launching combines the technical disciplines implicit in the design of fighter aircraft: aerodynamics, structure, flight control, and aircraft systems. In the framework of this conference, the discussion has particularly focused on flight dynamics. It covers: the specifications of the RAFALE naval launching; some related aspects at the aircraft catapult design: flight control system, improved performance systems (dihedral launch, high-energy recovery rate); the ground tests; and the tests at sea.

X-31: A PROGRAM OVERVIEW AND FLIGHT TEST STATUS

Ross, H., Deutsche Aerospace A.G., Germany; Neuberger, U., Deutsche Aerospace A.G., Germany; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 7 p; In English; See also 19950025568; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

The objective of the X-31 program (the first international US/German experimental program) was to develop a new fighter that can execute tactical maneuvers up to an angle of attack (AOA) of 70 degrees (which is far beyond the stall AOA) without the pilot losing control of the aircraft (poststall capability, PST). This capability extends aircraft performance with respect to deceleration capability, turn rate and radius, and pointing capability for weapon firing considerably and results in a distinctive improvement of the tactical advantages in close-in combat. The prerequisite for these capabilities is the use of thrust vector control to boost or even replace the aerodynamic controls which lose their effectiveness at low speeds and in the poststall regime. The technical development of the PST capability requires the application of new technologies in the areas of aerodynamics (separated vortex flow), propulsion (inlet aerodynamics and jet deflection) and in particular, flight control (unstable configurations, digital flight control systems, integrated thrust vector control). Flight test results of the X-31 showed that the four important basic maneuvers (safe flight and maneuvering at 70 deg. AOA, 360 deg. rolls about the velocity at 70 deg. AOA, poststall maneuvers at high load factors, and the 180 deg. J (or Herbst) turn with extremely small turn radii and high turn rates) have been successfully demonstrated. In Nov./Dec. 1993 the flight envelope was extended into the supersonic and flights with a helmet mounted display (HMD) were conducted. This paper gives an overview of the X-31 program and the results of the test flights.

INTEGRATED SPECIAL MISSION FLIGHT MANAGEMENT FOR A FLIGHT INSPECTION AIRCRAFT

Redeker, A., Aerodata Flugmesstechnik G.m.b.H., Germany; Haverland, M., Aerodata Flugmesstechnik G.m.b.H., Germany; AGARD, Dual Usage in Military and Commercial Technology in Guidance and Control; Mar 1, 1995, 3 p; In English; See also 19950026705; Copyright; Avail: CASI; A01, Hardcopy; A02, Microfiche

Flight Inspection of military and civil radionavigation aids requires calibration aircraft with a complex mission equipment. The measurement patterns and their flight procedures differ from usual flight procedures, which cannot be performed with normal flight management/autopilot systems. On the other hand there is a requirement for an automatic guidance, in order to increase the reproducibility of calibration

results and to assist the crew operating in areas with high traffic density. Special mission flight management systems, which are available on the market, are not an elegant solution for flight inspection applications. The flight inspection system (FIS) contains already all elements of a flight management system (FMS), and the FIS has more comprehensive information on navigational data. The system approach of an integrated FIS/FMS system is presented, where special mission profiles are generated and interfaced to the autopilot. Flight test results and operational experience are reported.

PRESENT CAPABILITIES OF PREDICTING TWO-DIMENSIONAL DYNAMIC STALL

Ekaterinaris, J. A., Naval Postgraduate School, USA; Srinivasan, G. R., Sterling Software, Inc., USA; McCroskey, W. J., Army Aviation Systems Command, USA; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 23 p; In English; See also 19960003572; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The current status of computational methods in predicting dynamic stall is summarized. Computed results for unsteady, attached and separated, turbulent flows over airfoils undergoing oscillatory motion are presented. The compressible form of the Reynolds-averaged Navier-Stokes equations is used. Numerical integration of the governing equations is performed with an approximately factorized algorithm. The inviscid fluxes are evaluated using both central differences and an upwind-biased method. The ability of several turbulence models, widely used for the prediction of steady flows, is tested for the unsteady flows. Solutions computed with algebraic, one-equation, and two-equation turbulence models are compared with experimental data. For the fully turbulent flows with tripped boundary layer most turbulence models predict lift hysteresis reasonably well. Some turbulence models give good qualitative agreement with the measured drag and pitching moment hysteresis loops. The computed results for untripped flows, where a small transitional region at the leading edge exist, show that the key to the accurate prediction of the unsteady loads at stall conditions is the modeling of this transition region at the leading edge. A simplified criterion for the transition onset is used, and the transitional flow region is computed with a modified form of the turbulence model. The computed solutions, where the transitional flow region is included, show that the small laminar/transitional separation bubble formed during the pitch-up motion has a decisive effect on the near wall flow and the development of the unsteady loads. Finally, the numerical solutions show some sensitivity to the kind of numerical algorithm used despite the reasonably fine grids used.

FORWARD FLIGHT ROTOR AIRLOADS PREDICTIONS USING A COUPLED NAVIER-STOKES/FULL-POTENTIAL ANALYSIS

Berezin, C., Sikorsky Aircraft, USA; Sankar, L., Georgia Inst. of Tech., USA; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 10 p; In English; See also 19960003572; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

Unsteady airloads predictions from a hybrid Navier-Stokes/full-potential code for a model UH-60A rotor in forward flight are presented. The code splits the physical domain into a near blade viscous region surrounded by an inviscid potential region. The two regions are coupled through boundary conditions on the interface surface separating them. In addition, the interface surface has been modified to dynamically adjust its position normal to the blade surface depending on the instantaneous distribution of vorticity in the viscous region. This allows roughly a 50 percent reduction of CPU time usage when compared with a standalone Navier-Stokes code. Comparison of the hybrid code surface pressures with the standalone Navier-Stokes results shows good agreement in quadrants one, two, and four. The

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

hybrid code overpredicts the extent of a separated region in the third quadrant which suggests further improvements to the unsteady interface boundary conditions are needed.

This paper serves to inform the reader about in-flight research at DRA Bedford on the DRA's Aeromechanics Lynx Control and Agility Testbed (ALYCAT) using instrumented main and tail rotor blades. The paper describes the instrumentation, data analysis techniques and flight test programs, with the initial results from recent trials using instrumented main rotor blades on ALYCAT presented for the first time, and results from the earlier trials using an instrumented tail rotor blade presented in more detail.

The study of the aerodynamic burden-sharing on a rotor of operative helicopter in hovering, is approached in this paper by means of a new technique of exploration by laser velocimetry, coupled to assessment of momentum and Kutta (KMA Method). The effectiveness of this method is evaluated for various parametric configurations of the hovering.

This paper examines the helicopter/ship dynamic interface by combining both experimental and numerical analyses. The flow field over the flight deck of a frigate model was mapped experimentally in a wind tunnel using both stationary and flying hot-film sensors. Using the velocity time-histories measured in the wind tunnel, a numerical representation of the airwake which shares the same spectral characteristics was generated. A blade-element model for the main rotor of a helicopter was then 'flown' in this numerical airwake to determine the

steady and unsteady loads acting on the rotor. The results of a set of test simulations indicate: (1) that an increase in unsteady rotor loads occurs when spatial cross-correlation functions are included in the generation of the numerical flow field; (2) that the fluctuating vertical velocity has a greater effect on the unsteady rotor loads than the fluctuating horizontal velocity; and (3) that the spectra of unsteady forces and moments show similar broadband and resonant behavior at different free-stream velocities.

A THEORETICAL AND EXPERIMENTAL INVESTIGATION INTO THE ROTOR BLADE AEROELASTIC BEHAVIOUR OF A SHIP-BORNE HELICOPTER DURING ROTOR ENGAGEMENT AND BRAKING

Newman, S. J., Southampton Univ., UK; AGARD, Aerodynamics and Aeroacoustics of Rotorcraft; Aug 1, 1995, 10 p; In English; See also 19960003572; Sponsored by the DRA; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

Under normal operating flight procedures, a helicopter main rotor revolves at a strictly controlled speed. The centrifugal forces generated keep balance with the aerodynamic loads with the result that the rotor blade motion, in particular the blade flapping, is maintained under control. To reach the normal rotational speeds the rotor must of course pass through lower speeds, both during acceleration and deceleration, and during these periods the blades can fall prey to the phenomenon of blade sailing. With this, not inconsiderable aerodynamic loads can be generated when the helicopter is operating in high winds and with the reduced centrifugal forces because of the lower rotor speeds, the blade flapping motion can build up to dangerously large deflections.

INTRODUCTION TO FLIGHT TEST ENGINEERING INTRODUCTION A LA TECHNIQUE DESSAIS EN VOL

Stoliker, F. N., Stoliker (F. N.), USA; Sep. 1995; 458p; In English Report No.(s): AGARD-AG-300-VOL-14; ISBN 92-836-1020-2; Copyright Waived; Avail: CASI; A20, Hardcopy; A04, Microfiche

This is the Introductory Volume to the Flight Test Techniques Series. It is a general introduction to the various activities and aspects of Flight Test Engineering that must be considered when planning, conducting, and reporting a flight test program. Its main intent is to provide a broad overview to the novice engineer or to other people who have a need to interface with specialists within the flight test community. The first two Sections provide some insight into the question of why flight test and give a short history of flight test engineering. Sections 3 through 10 deal with the preparation for flight testing. They provide guidance on the preliminary factors that must be considered; the composition of the test team; the logistic support requirements; the instrumentation and data processing requirements; the flight test plan; the associated preliminary ground tests; and last, but by no means least, discuss safety aspects. Sections 11 through 27 describe the various types of flight tests that are usually conducted during the development and certification of a new or modified aircraft type. Each Section offers a brief introduction to the topic under consideration, and the nature and the objectives of the tests to be conducted. It lists the test instrumentation (and, where appropriate, other test equipment and facilities) required, describes the test maneuvers to be executed, and indicates the way in which the test data is selected, analyzed, and presented. The various activities that should take place between test flights are presented next. Items that are covered are: who to debrief; what type of reports to send where; types of data analysis required for next flight; review of test data to make a comparison to predicted data and some courses of action if there is not good agreement; and comments on selecting the next test flight. The activities that must take place upon completion of the test program are presented. The types

of reports and briefings that should take place and a discussion of some of the uses of the flight test data are covered. A brief forecast is presented of where present trends may be leading.

Several countries have been experiencing aging aircraft related problems in their military fleets, particularly among their military transport aircraft. The most troubling aging aircraft structure-related issue is widespread fatigue damage (WFD), sometimes termed as multiple site damage, whose onset due to fatigue causes a dramatic structural strength reduction. Invariably, when WFD occurs, the affected model in the fleet is subjected to an extensive modification program which is almost always expensive and time-consuming. A Specialists' Meeting on the subject was held in order to explore ways and means to quantitatively predict structural degradation on account of WFD as a function of usage and when WFD is likely to occur.

OVERVIEW OF WIDESPREAD FATIGUE DAMAGE: RISK ASSESSMENT METHODOLOGY

Lincoln, John W., Aeronautical Systems Div., USA; Widespread Fatigue Damage in Military Aircraft; Dec. 1995; 12p; In English; See also 19960020736; No Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The USA Air Force has used the probabilistic method to determine the onset of widespread fatigue damage in its aircraft for the past twenty years. They have focused their efforts on the loss of damage tolerance capability for both monolithic and fail-safe structures. The application of the probabilistic method requires that the appropriate data bases be estimated. The USAF generated these data bases through teardown inspections and from the operational usage tracking programs. The purpose of this paper is to provide an overview of the methodology for the probabilistic approach through risk assessments performed on USAF aircraft. These risk assessments provided the basis to make the appropriate aircraft modifications for elimination of this problem. In addition, a sample problem illustrating some of the essential data requirements for these analyses and the consequences of the results will be discussed.

A SPECIAL UNIAXIAL COUPON TEST SPECIMEN FOR THE SIMULATION OF MULTIPLE SITE FATIGUE CRACK GROWTH AND LINK-UP IN FUSELAGE SKIN SPLICES

Eastaugh, G. F., National Research Council of Canada, Canada; Simpson, D. L., National Research Council of Canada, Canada; Straznicki, P. V., Carleton Univ., Canada; Wakeman, R. B., Carleton Univ., Canada; Widespread Fatigue Damage in Military Aircraft; Dec. 1995; 20p; In English; See also 19960020736; No Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper reviews the loading and fatigue characteristics of longitudinal fuselage splices, and presents a specification and design concept for a uniaxial coupon test specimen that is intended to simulate these characteristics at low cost relative to full-scale panel and fuselage test articles. In particular, the specimen is intended to simulate the initiation, growth and link-up of multiple site fatigue damage (MSD). This simulation cannot be done with conventional coupon splice specimens. For proof-of-concept testing, the MSD specimen

was tailored to be roughly representative of current narrow-body jet transport aircraft, using limited aircraft stress and other data available in the open literature. The results indicate that the specimen concept can fulfill its intended purpose. It would now be appropriate to apply the MSD specimen concept to a specific aircraft, in collaboration with the aircraft manufacturer. A procedure for tailoring the MSD specimen to a particular aircraft is proposed.

WIDESPREAD FATIGUE DAMAGE AND SINGLE MEMBER FAILURE PREDICTION OF MILITARY JET TRAINERS OF CZECH DESIGN AND PRODUCTION

Fidrnsky, Jiri, Aero Vodochody A.S., Czechoslovakia; Fiala, Jiri, Aero Vodochody A.S., Czechoslovakia; Widespread Fatigue Damage in Military Aircraft; Dec. 1995; 12p; In English; See also 19960020736; No Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Military jet trainers originally designed under safe life concept are approaching in a lot of cases their service life estimates, based on 20 year old analyses and tests. The fleet condition and upgraded service spectra evaluation enables a significant life extension, because of safety margins of former approach. The Czech designed and produced L-39/59 jet trainer has been submitted to the Aircraft Structure Integrity Program (ASIP) with the main goal to extend the service life. As an essential tool for confirmation of the results the full-scale tests have been used. Widespread fatigue damage (WFD) has arisen during the tests on several areas of primary structure, but at least three service lives were without significant damage. In one case there was the phenomenon limiting the fatigue life of the component. In other cases fatigue life was significantly influenced, but widespread fatigue can be used as an indicator of possible damage of a single load path. The acoustic loading was the source of the significant WFD of the engine air intake duct. That is the only WFD occurred in service. Analytical techniques failed in several cases in prediction of WFD so far, but prediction of damage propagation on the stiffened panels still continues. The inspection periods and repair techniques were verified during the tests. To avoid possible structure damage, nondestructive inspection and Individual Aircraft Tracing (IAT) were introduced into maintenance procedures. The skin damage, caused by WFD, was successfully repaired in several cases by composite patches.

ANALYSIS OF AIRCRAFT PANELS WITH WFD, BASED ON THE ELASTIC PLASTIC FINITE ELEMENT ALTERNATING METHOD (EPFEM) AND T*(SUB EPSILON) INTEGRAL

Pyo, C. R., Georgia Inst. of Tech., USA; Okada, H., Georgia Inst. of Tech., USA; Atluri, S. N., Georgia Inst. of Tech., USA; Widespread Fatigue Damage in Military Aircraft; Dec. 1995; 10p; In English; See also 19960020736; No Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Structural integrity evaluation of aging transport aircraft structures is extremely important to insure their economic and safe operation. In an airliner fuselage, pressurization causes stresses in the shell structure. The stiffening elements, such as stringers, frames and tear strips, take a part of the load but the major fraction is taken by the skin, for a typical fuselage structure. A typical situation of Multiple Site Damage (MSD) is the existence of multiple cracks of arbitrary lengths emanating from a row of fastener holes in a bonded, riveted joint in a pressurized fuselage. This problem has been the object of a number of studies in assessing the structural integrity of aging airplanes because the residual strength of a structure with a single crack may significantly be reduced by the existence of adjacent smaller cracks. In this paper, new analytical methods (Elastic Plastic Finite Element Alternating Method (EPFEM)) for predicting the residual strength of a ductile panel with a row of cracks, and their results are presented. The alternating method is based on an analytical modeling of cracks and on an iterative procedure to satisfy the required boundary conditions for the body under consideration. A finite element solution is required only for the problem without cracks. A very fine mesh pattern

used in usual FEM is not necessary. The EPFEAM that uses the elastic alternating method in conjunction with the initial stress method as an elastic plastic algorithm, is extended in this paper to analyze stably propagating MSD cracks and their link up. The crack extension is modeled by releasing the cohesive traction ahead of the crack-tip based on an analytical solution. Thus, unlike the more common finite element nodal release technique, the amount of crack growth at any time is independent of the finite element mesh discretization. Among the various fracture criteria to model the crack growth, the T^* (sub epsilon) integral, based on the equivalent domain integral (EDI), is employed. The procedures of the elastic-plastic finite element alternating method (EP-FEAM) are described in this paper for stationary as well as for stably propagating MSD cracks. Some numerical examples are presented, illustrating the residual strength estimations for a panel with MSD. The analytical results based on the stationary and stable crack propagation analyses are compared, and their differences in their residual strength predictions are also discussed.

RISK ANALYSIS IN THE PRESENCE OF CORROSION DAMAGE

Berens, A. P., Dayton Univ. Research Inst., USA; Burns, J. G., Wright Lab., USA; Dec. 1995; 10p; In English; See also 19960020736; No Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

To quantify the potential damaging effects of corrosion in an aging fleet of aircraft, a structural risk analysis computer code was used to calculate the probabilities of fracture under statically defined corrosion scenarios. The analysis was performed using results from a damage tolerance evaluation of a critical location on an observation class, ground support aircraft. A realistic equivalent initial flaw size distribution was assumed for the start of the analysis. Corrosion condition, defined in terms of five and ten percent thickness loss, were imposed for two subsequent periods in the life of the aircraft. The effects of detecting and repairing or not detecting the corrosion were modeled. For the scenarios and conditions assumed in this analytical sensitivity study, undetected corrosion effects led to order of magnitude increases in risk. These results indicate that corrosion damage could well impact safety in the aging aircraft fleets.

The paper examines the adequacy of the U.S. Air Force damage tolerance inspection criterion for protecting the safety of the flight of an aging military trainer aircraft. This is done through a risk assessment on the basis of cracks found in teardown inspections of retired wings. The crack population is combined with stress probabilities representing service experience to determine single flight probability of failure and the single aircraft probability of failure at a given time. These quantities are then used as a basis for judging the required inspection interval. For the case studied, the 0.9 probability of detection inspection criterion in the Air Force damage tolerance requirements may be unconservative.

As part of a structural assessment of the C-141 aircraft for life extension feasibility, the USA Air Force Scientific Advisory Board (SAB) directed a teardown inspection on a high time C-141 inner wing lower surface. The teardown inspection was performed at Lockheed Aeronautical System Company (LASC), Marietta, GA, in 1993. This paper will address the following: (1) why was the teardown required?; (2) the condition of the aircraft before the teardown; (3) teardown procedure; and (4) how the results of the teardown were used. The teardown program was performed over six months. Eight thousand, seven hundred and sixty-two holes on the right wing were inspected by automatic bolt hole eddy current (ABHEC). One hundred and fifty-three flaws were detected initially, with the final number of two hundred and eighty-nine confirmed flaws. The results of the teardown were used by the Air Force to carry out an inspection/repair program that maintained a safe operational environment for the C-141B aircraft.

AVOIDING WFD: A GUIDE TO THE FATIGUE DESIGN REGULATIONS FOR BRITISH MILITARY AIRCRAFT

Cardrick, Arthur, Defence Research Agency, Farnborough, UK; Dec. 1995; 12p; In English; See also 19960020736; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The loss some years ago of a large section of the cabin roof from an aging Boeing 737 thrust the specter of Widespread Fatigue Damage (WFD) into the public domain and gave new impetus to regulations for preventing fatigue life from being undermined by corrosion or repairs. This paper begins with some examples of major fatigue tests in which classical WFD failures have occurred and goes on to consider how the Fatigue Regulations for British Military Aircraft combat the threat presented by WFD as well as the wider threats presented by corrosion, repairs and increases in the severity of service loading. The paper closes by illustrating how the antithesis of WFD - damage concentrated in just one location - might be used to improve the safety and durability of future designs.

DAMAGE TOLERANCE TO WFD (WIDESPREAD FATIGUE DAMAGE) ON COMBAT AIRCRAFT: AN APPLICATION TO A METALLIC WING LOWER PANEL

Cazes, R. J., Dassault Aviation, France; Goerung, F., Dassault Aviation, France; Widespread Fatigue Damage in Military Aircraft; Dec. 1995; 14p; In English; See also 19960020736; No Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Maintaining the structural integrity of aircraft in prolonged service requires consideration to be given to inspections for detecting possible multiple damage. This paper presents an assessment of the structural behavior of a (metallic) underwing panel of which several bays between stiffeners may be corroded both on their surface and within their thickness. The analysis of tolerance to damage highlights the importance of statistical feedback from inspections for establishing hypothesis of structural damage with which to predict behavior, and highlights the particular attention to be paid to structures in a saline or corrosive environment.

FATIGUE DAMAGES DURING TORNADO MAF TEST

Broecker, W., Industrieanlagen-Betriebsgesellschaft m.b.H., Germany; Buderath, M., Daimler-Benz Aerospace A.G., Germany; Widespread Fatigue Damage in Military Aircraft; Dec. 1995; 8p; In English; See also 19960020736; No Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Some of the fatigue damages which have occurred during the major airframe fatigue test (MAF-Test) of TORNADO fighter aircraft seemed to be wide spread fatigue damages (WFD). These damages accompanied by results from coupon tests will be presented and analyzed in this paper. This paper will confirm that the load transmission in bolted splice sections is a rather complex phenomenon. The fatigue behavior of a bolted joint/splice is dependent on many parameters, as there are different designs, materials and fastener types used. Because there is still not abundance of information available about the WFD problem, the inspections of bolted joints with respect to aging aircraft should be based on coupon tests or better still on full scale fatigue tests.

DAMAGE TOLERANCE EVALUATION ON THE A7-P AIRCRAFT CONSIDERING THE POAF USAGE

deFreitas, Manuel, Instituto Superior Tecnico, Portugal; Fonseca, Agostinho, Instituto Superior Tecnico, Portugal; Goncalo, Humberto, Portuguese Air Force, Portugal; Pires, Carvalho, Portuguese Air Force, Portugal; Widespread Fatigue Damage in Military Aircraft; Dec. 1995; 8p; In English; See also 19960020736; No Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

An exploratory and preliminary damage tolerance evaluation on the A7-P Corsair is presented. The stress data was obtained through the data acquisition system installed in two aircraft in PoAF fleet. Forman's law and Wheeler retardation model were used on a crack propagation simulation of cracks emanating from a hole in the wing lower skin. The material fatigue data was originally generated by

Vought Corporations, the aircraft manufacturer. The results show the influence of multiple crack initiation and propagation on the predicted fatigue life of the A7-P aircraft.

Most attention to Widespread Fatigue Damage (WFD) has for obvious reasons been focused on the transport aircraft category. For such aircraft many of the prerequisite for WFD to occur are present. Colinear structure, stress field close to uniform, thin sheet sections and almost constant amplitude loading are all conditions that make some primary transport aircraft structures prone to develop WFD. In combat aircraft, these conditions are not so easily identified and not always present all together at the same time. An inventory has been done of combat aircraft wing-structure that may have the potential to develop WFD. Saab combat aircraft designed during the 50's and 60's have been studied. Structures have been selected according to a set of conditions that may be important for WFD to develop. The design and stresses of such structure are discussed in view of available full-scale test results of presence or non-presence WFD.

A range of laboratory specimens, representative of pressurized fuselage structures, were tested under constant amplitude loading to provide data for comparison with theoretical predictions. A proportion of specimens were subjected to single overload cycles. The theoretical model was based on recognized methods of contemporary fracture mechanics, allied to a simple but effective technique for modeling the growth behavior of a fatigue crack following an overload cycle. Good agreement was noted between predictions and experimental results, and recommendations for further development of the model are being formulated.

The papers presented at the AGARD Structures and Materials Panel's Specialists' Meeting on Aeroservoelastic Testing and Data Analysis, held in Rotterdam in May 1995 are included. Flutter is a potentially catastrophic aeroelastic dynamic instability. Flight flutter tests are conducted to demonstrate freedom from flutter for critical aircraft conditions and to derive data to validate the flutter analysis. Active control systems (ride control, gust load alleviation, flutter stabilization, etc.) add to the scope and complexity of these tests in that control system instability due to aeroservoelastic interactions must

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

also be considered. The conclusions of the meeting are that most of the tests need improvements, some tests should be better exploited, and at least one test, the in-flight measurement of unsteady air loads, should become standard practice to close a gap in the logic of flutter certification.

This paper reviews the test techniques developed over the last several decades for flight flutter testing of aircraft. Structural excitation systems, instrumentation systems, digital data preprocessing, and parameter identification algorithms (for frequency and damping estimates from the response data) are described. Practical experiences and example test programs illustrate the combined, integrated effectiveness of the various approaches used. Finally, comments regarding the direction of future developments and needs are presented.

FLUTTER FLIGHT TEST OF THE RANGER 2000 AIRCRAFT

Weiss, F., Daimler-Benz Aerospace A.G., Germany; Schweiger, J., Daimler-Benz Aerospace A.G., Germany; Hoenlinger, H., Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Germany; Nov. 1995; 10p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper describes the flight flutter test activities for the RANGER 2000 training aircraft, which was jointly developed by DASA and Rockwell International between 1991 and 1994 as a competitor for the next generation U.S. Air Force and Navy Joint Primary Advanced Training System (JPATS). After a brief description of the program and the main aircraft features, an overview of the aeroelastic analysis and the ground vibration tests during the design process are given. The report of the flight test activities is divided into the description of the test equipment, aircraft instrumentation, flight envelope, test procedures, realtime telemetry monitoring and post-flight data reduction. Typical time histories of response, frequency response functions, power spectra and typical plots of the frequencies and damping versus dynamic pressure are given. The flight test results in combination with the aeroelastic analysis are discussed at the end.

In modern flutter testing of aircraft artificial excitation is applied. A recently developed aerodynamic vane has been tested in a preliminary flight test to become familiar with installation and use. Two of these vanes have been applied at flutter testing of an configuration of the Fokker 50 Mk2S. Some results of the flight tests and properties of the aerodynamic vane are highlighted.

US AIR FORCE/DEI FLUTTER EXCITER TEST PROGRAM

Shirley, B. M., Department of the Air Force, USA; Anderson, E. L., Tybrin Corp., USA; Advanced aeroservoelastic testing and data analysis; Nov. 1995; 10p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

USA Air Force (USAF) testing of the Dynamic Engineering Incorporated (DEI) flutter exciter was conducted in Jul. - Sept. 1993, using pylon-mounted exciters on an existing F-16A flutter test aircraft. The intent was to evaluate the system as a low-cost, easily-installed alternative to the existing aircraft flight control integrated systems. A dual exciter system with an exciter mounted on the outboard side of each weapons pylon (aircraft weapons stations 3 and 7) was flight tested in conjunction with the existing integrated Flutter Exciter System (FES). The existing F-16 system provides excitation via the flaperons; it is capable of symmetric and antisymmetric sweeps and bursts of up to 20 Hz for selectable time durations. Testing of the DEI flutter exciter system was limited to matching FES time/frequency capabilities, although it has greater frequency response and time duration capabilities. A one-for-one comparison of excitation levels, frequency content and damping values was made at various Mach/airspeed/altitude combinations for five different aircraft/weapon configurations, three of which are presented herein. Conclusions are drawn regarding (1) the use of the DEI exciter in a high-q environment; and (2) its application as an alternative excitation method.

STATUS ON STRATO 2C FLIGHT FLUTTER TESTING ACTIVITIES

Kiessling, F., Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Germany; Rippl, M., Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Germany; Hoenlinger, H., Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Germany; Nov. 1995; 8p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The STRATO 2C aircraft is currently being developed for manned stratospheric research missions up to 80,000 ft. It is powered by two 330 kW turbo-charged piston engines. The requirements for flight endurance, altitude, payload, and operating range can only be met if high aerodynamic quality, high propulsion efficiency, and low empty weight are achieved simultaneously. The large wing span (56.5 m) and aspect ratio (21.3) result from aerodynamic optimization. Carbon fiber composites are applied to reduce weight and deflections. Possible aeroelastic problems are dealt with during aircraft development. This paper gives an overview on these activities. When considering its flutter proneness, STRATO 2C may be compared with modern high-performance sailplanes. However, this analogy fails when taking into account its size, operating altitude, and large wing mounted nacelles with pusher propellers. In the early stages, a modal survey test on the stabilizer spar box similar to that of the wing was performed to check finite-element modeling assumptions. The idealization of the complete aircraft leads to a verified model which is used for aeroelastic predictions for various configurations without excessive test efforts. A ground vibration test on the proof-of-concept aircraft serves as the main experimental data base. The flutter analysis includes the design of control surface mass balance and attachment flexibility. The five-bladed wood/composite propellers with a size of 6 m in diameter are constrained to minimum weight. Two types of aeroelastic vibrations were observed in the first windtunnel tests and were identified as blade flutter and forced response at yawed flow conditions, respectively. An improved design was checked by analytical comparison based on modal test data. Whirl flutter is possible with large elastically mounted propellers operating at high advance ratios. This subject is briefly addressed in this paper.

A full scale unmanned air vehicle (HATT-X) was tested in an open jet wind tunnel facility. Strain gauges were installed on the canard shafts to measure the unsteady aerodynamic loads. The data was recorded on a high speed data acquisition system for off-line analysis. High speed photography was also used to study the canard motion. A destructive 57 Hz canard flutter was observed at a Mach number of approximately 0.75 and dynamic pressure of 5.95 psi for a canard incidence angle of approximately 4 deg. A mass balances and stiffer canard was manufactured and installed on the HATT-X. A flight test on the modified HATT-X was conducted. Approximately 2 second after initiation of the stage 7 motor burn, large vertical oscillations of the port side canard were detected, followed by the structural failure of the canard linkage system in the forward fuselage. At the failure point the vehicle was decelerating after the rocket motor burn and the Mach number was approximately 0.75. Failure of the canard system was investigated and where possible comparisons were made of the aeroelastic behavior in the wind tunnel and flight tests of the two canards that are structurally different.

An approach has been developed which uses optimization methods to automate wind tunnel model design. The model design process has been divided into separate stiffness design and mass design stages. Then, a sample structure was manufactured and subjected to static and modal testing using laser holographic techniques. Optical test methods are well suited to testing subscale models. A single image shows either static or dynamic out of plane deflections for the entire model. These methods reduced the time required to characterize the test specimen compared to more conventional methods and did so with improved accuracy.

This article presents a review and assessment of the various techniques that have been used to estimate modal parameters from flight flutter test data. The relative advantages and disadvantages of the methods are examined, with particular emphasis being given to their suitability for analyzing flutter test data. The problems associated with analyzing non-linear and aeroservoelastic test data are highlighted. Recent advances in modal parameter identification are

considered in terms of their relevance to flight flutter testing. Finally, future requirements for the analysis of flight flutter test data are discussed.

CF-18 FLIGHT FLUTTER TEST (FFT) TECHNIQUES

Dickinson, M., Canadair Ltd., Canada; Nov. 1995; 10p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The paper describes Canadair's role in the flight flutter testing of the CF-18 aircraft for the Canadian Forces. The flight test programs are flown from AETE Cold Lake Alberta, and are a partnership between Canadair and AETE. The 1992 category 2 480 gallon EFT FFT program is used as a detailed example of this Canadair role. The paper emphasizes the FFT techniques currently employed, and the difficulties encountered due to non-linear modal behavior and a transonic EFT buffet condition. The test program marked the first FFT application of AETE's LMS frequency analysis system. The paper describes the user programs developed to tailor and automate this system for CF-18 FFT use. The programs are written in the LMS UPA language and were largely developed as the FFT program progressed. The results from two separate FFT data reduction techniques (dwell-decay PSD, and FRF / MLE curvefitting) are directly compared with the preflight FEM predictions. The differences in the two sets of FFT results are explained by studying a simple Log-Dec analysis of a response decay.

A MAXIMUM LIKELIHOOD PARAMETER ESTIMATION TECHNIQUE TO ANALYSE MULTIPLE INPUT/MULTIPLE OUTPUT FLUTTER TEST DATA

VanderAuweraer, H., LMS International, Belgium; Guillaume, P., Vrije Univ., Belgium; Nov. 1995; 8p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

In this paper, the formulation of the maximum likelihood SISO (Single Input / Single Output) estimator (ELIS) is generalized for MIMO (Multiple Input / Multiple Output) systems. The behavior of the two ML estimators is compared when applied to real and synthetic data. The following conclusions can be drawn. When a mechanical structure is excited at different places or/and the response is monitored at several points, the MIMO estimator can extract more information out of the measurements than the SISO estimator. The gain obtained by using the MIMO estimator is essentially due to the assumption of global parameters in the transfer function matrix. The result is independent of the estimation method used. Usually it is assumed that the transfer functions of the transfer function matrix equation all have common poles. The more links the better the interaction among the measurements. In one of the test cases, it was therefore possible to estimate a pole-zero pair which was completely hidden by the noise thanks to the information present in the input-output measurements related to the other transfer functions. Due to the relatively large amount of data processed by the MIMO estimator, the asymptotic properties of the ML estimators are reached sooner. When the input signals are correlated, the SISO estimator cannot be used without introducing supplementary errors.

A number of methods developed with the aim of improving the analysis and interpretation of flight flutter test data are described. The approaches are divided into improved curve fitting techniques and methods for enabling increased confidence in the flutter clearance procedure. Real and simulated flight flutter data are used to illustrate the various approaches.

Solving practical problems of modern aeroservoelasticity (ASE) presumes accomplishing reasonable synthesis and reliable analysis of nonlinear analog-digital multi-dimensional electromechanical objects characteristics in frequency and time domains. This paper briefly describes the system of experimental and analytical research and certification used in the Russian aircraft industry to ensure aircraft safety from vibrations of various types due to the interaction between the airframe and flight control system as well as active control of aeroelastic dynamic deformations. The system provides qualitative determination and analysis of ASE characteristics for all aircraft development stages. Some real results obtained in ASE research programs on wide body civil and aerospace aircraft are presented as an illustration.

The paper gives a short review of all flutter-relevant tests of an a/c and discusses differences between the wanted and the reached reliability of the measured data. This includes weight measurements, stiffness tests, actuator impedance tests, tests of the Electronic Flight Control Systems (EFCS), Ground Vibration Tests (GVT), Flight Vibration Tests (FVT), in-flight measurements of unsteady airloads, and safety tests for active control systems. The conclusions are that most of the tests need some improvements, some tests should be better exploited, and at least one test, the in-flight measurement of unsteady airloads, should become standard practice to close a gap in the logic of flutter certification.

A computer system for analysis and display of flutter parameters during flight flutter testing of an unstable digitally controlled fly-by-wire combat aircraft is presented. The system is being developed by BAE in conjunction with Parsytec GmbH, a computer company specializing in parallel processing hardware and software and applied to the Eurofighter 2000 (EF2000). The benefits will increase aircraft safety by identifying critical parameters involved in the flutter mechanisms during flight flutter testing, by increasing the visibility of data to the test engineer. The Parsytec system, which is part of the flight test ground station, is fully integrated with the telemetry facility and is capable of analyzing, confidencing and displaying test data for comparison with prediction in near-real time. This facility, which includes parallel processing transputers combined with high performance digital signal

processing devices, will enable the engineer to assess analyzed data quickly and efficiently in order to decide whether or not the aircraft can safely progress the envelope expansion. In addition, an aircraft excitation system is being developed which will permit predefined waveforms, generated within the Flight Control Computers (FCC) to be summed into the Flight Control System (FCS) actuation loops under cockpit control. The overall clearance philosophy for identifying critical flutter parameters through calculations, ground testing, and flight testing is also presented.

Aircraft parameter estimation is probably the most outstanding and illustrated example of the system identification methodology, which provides answers to the age-old inverse problem of model determination and validation given a set of observations. After providing a brief account of historical background, the paper traces chronologically the evolution of flight vehicle system identification starting from determination of aircraft frequency and damping ratio from flight data in the early twenties to the present day advanced applications such as estimation of high fidelity aerodynamic data bases for flight simulators or evaluation of highly augmented unstable flight vehicles of unconventional configurations. Through selected examples, it is demonstrated that the system identification methods have reached a maturity level that makes them a powerful and useful tool to support not only research but also industry activity in model validation, handling qualities evaluation, control law design, and flight vehicle design, and thus contribute significantly to risk and cost reduction in the optimal deployment of the existing aircraft and in the development of new generation aircraft. Although the paper focuses mainly on the applications in the area of flight mechanics, some aspects of interdisciplinary flight vehicle modeling, for applications such as aeroservoelasticity or high bandwidth rotorcraft modeling, are addressed as well.

ELEMENTS OF THE B-2 FLIGHT FLUTTER TEST PROGRAM**

Britt, R. T., Northrop Grumman Corp., USA; Winther, B., Northrop Grumman Corp., USA; Nov. 1995; 8p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This presentation described the basic test techniques and analysis methodology utilized during the execution of the flutter flight test program on the USAF/Northrop B-2 stealth bomber aircraft. Key elements of the program that were presented included: excitation systems that used control surfaces and turbulence (with comments on actuator capabilities, bandwidth and rates, and digital system effects); the use of an on-board test panel to provide excitation inputs (sine sweep, dwells, and random inputs with full control over frequency, magnitude, rate, and spectrum shape); the simultaneous recording of all instrumentation signals (distributed accelerometers, strain gauges, and control surface deflections); methodologies used to provide modal frequency and damping estimates; and real-time data acquisition/analysis procedures with point-to-point clearance.

GROUND STRUCTURAL COUPLING TESTING AND MODEL UPDATING IN THE AEROSERVOELASTIC QUALIFICATION OF COMBAT AIRCRAFT

Vaccaro, V., Alenia Aeronautica, Italy; Becker, J., Daimler-Benz Aerospace A.G., Germany; Nov. 1995; 12p; In English; See also 19960020814; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper is concerned with the role played by the ground Structural Coupling Test (SCT) and the update of the aeroservoelastic model in the qualification process of a modern combat aircraft. Most of modern aircraft are equipped with fly-by-wire and electronic Flight Control Systems (FCS). The problem of interaction between the dynamic response of the airframe and the FCS is usually solved through an appropriate set of notch filters, designed to attenuate the level of structural vibrations picked up by the FCS sensors. Fundamental part of the qualification of the notch filter set is the ground testing activity, generally known as ground structural coupling test. The main subject of this paper is the description of the test procedure followed for a delta-canard fly-by-wire aircraft. The peculiar aspect of this test was the identification of the coupling characteristics of the aircraft in the configuration with external stores. The final part of the paper deals with the utilization of the test results in the updating of the aeroservoelastic model. Emphasis is placed upon the necessity of an adequate model, in order to reduce the test activity to a limited set of external store configurations.

The Structures and Materials Panel of AGARD sponsored a Workshop focusing on the various vibrational and stability problems (e.g. shimmy, antiskid induced vibrations) that must be considered in the early design phase of landing gear systems, especially problems which are related to vibrations of the combined structural system formed by the landing gear, its tires and the flexible aircraft structure. The intention was to indicate the impact of (combined) landing gear/ aircraft vibration problems on aircraft design and to discuss the state-of-the-art technology in this area and to define possible future steps of development.

PRELIMINARY DESIGN OPTIMIZATION OF CARRIER AND LAND BASED FIGHTER LANDING GEARS

Crenshaw, B. M., Lockheed Martin Aeronautical Systems, Marietta; Brown, Susan C., Lockheed Martin Aeronautical Systems, Marietta; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 16p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The differences in requirements of land based (LB) and carrier based (CB) aircraft landing gear are reviewed with respect to landing impact and ground surface roughness. Frequently the issue of operational roughness requirements vs. 'taxi' requirements arises. More often, it seems, attention is being focused on operational runway roughness requirements. The MILSPEC roughness amplitudes and wavelengths may not represent the operational capability of an aircraft when combined sources of loading are considered. There are severe

loads on both main and nose gears during landing rollout on a rough runway surface if braking is used; however, levels of braking and roughness combinations are not always clearly defined in procurement specifications. The more robust landing gears sized for carrier operations are examined to determine their potential operational performance for land based roughness levels when combined loads from rollout braking are considered. While the weight penalty associated with carrier qualified landing gears is commonly recognized, and weight efficiency requirements of fighter aircraft may ultimately outweigh cost considerations for commonality of landing gear components, it is nevertheless worthwhile to consider methods for reducing costs through multiple application designs and parts usage. Although without great previous success, multi-service application of designs has long been an attractive concept. If severe runway roughness capability is considered as an operational requirement for land based gears, the weight obstacles to common landing gears may diminish. A hypothetical future fighter aircraft is utilized to compare runway roughness capability of gears sized for carrier landing and arrestment loads with gears sized exclusively for land based use, to compare relative landing gear weights, and to develop concepts of landing gears with the potential of multi-service usage. A simple forward retracting vertical post strut arrangement has been examined from a conceptual standpoint for low cost production in two stroke lengths.

A review of two different landing gear shimmy mathematical models is presented. One model uses the Moreland tire model and the other model uses the Von Schlippe-Dietrich tire model. The results of a parametric study using these models is presented indicating the sensitivity of various parameters to numerical variation. An identification of stability critical parameters in the models is given. Three different aircraft landing gear shimmy data sets are reviewed and model stability predictions are discussed. A comparison is made with actual experimental results. One of these data sets indicates the nonlinear variation of various input parameters as a function of strut stroke. In the course of the presentation some design rules and cautions are suggested.

SELF-INDUCED OSCILLATIONS OF LANDING GEAR AS AN INTEGRAL LANDING GEAR AIRCRAFT SYSTEM PROBLEM

Luber, W., Daimler-Benz Aerospace A.G., Germany; Kempf, G., Daimler-Benz Aerospace A.G., Germany; Krauss, A., Daimler-Benz Aerospace A.G., Germany; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 16p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

This paper treats three topics: Two of the topics deal with seemingly self-induced oscillations observed during aircraft and subsystem development tests. The third topic gives a short overview on procedures to treat shimmy as a 'flexible landing gear on flexible aircraft' problem. The topic treated in section 2 (Shimmy on Nose Landing Gear) presents a case observed in taxi tests of a prototype aircraft. Although specific shimmy calculations were not performed for this case, there are indications that a purely lateral/torsional tire model would possibly not have shown the instability observed. Appendix A gives some evidence therefore. Section 3 (Brake Torque Oscillations at Brake Initiation) treats a case where quasi self-induced oscillations are caused by interaction of tyre circumferential force characteristics with the brake control system. Usual means to suppress shimmy (e.g. dampers, modification of landing gear geometry) are ineffective in this case. Landing gear vibrations may cause a variety of problems in the

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

rest of the aircraft. Section 4 (Integral Landing Gear/Aircraft Problem) presents a summary of potential problem ramifications. It also gives a short overview on a viable approach to treat landing gear shimmy in context with aircraft structure.

ANALYSIS AND CONTROL OF THE FLEXIBLE DYNAMICS OF LANDING GEAR IN THE PRESENCE OF ANTISKID CONTROL SYSTEMS

Denti, E., Pisa Univ., Italy; Fanteria, D., Pisa Univ., Italy; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 14p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

This work is part of research carried out to investigate the vibration problems due to coupling between the flexible dynamics of aircraft landing gear and the dynamics of antiskid control systems. The last objective is the development of new antiskid devices for the suppression of landing gear vibrations during braking. In the paper the above mentioned problems are described together with the models and methods available for their investigation. Preliminary results of the research are also presented. Namely, an analytical and numerical model of the tires in runway contact dynamics, that is one of the most critical models involved, is developed. A linearized model of the system composed of the wheel and the landing gear is developed and the system poles are investigated.

R., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 12p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

This paper presents results of research performed in the field of semi-active suspensions for advanced landing gears and optimization of their associated design parameters to achieve minimum weight, maximum comfort under strict requirements with respect to safety and even increase lifetime by reducing the loads during landing impact and taxiing. A detailed mechanical model is derived for an existing aircraft (AIRBUS A300) which will be used for simulating the standard design as well as the active optimized landing gear. The simulation is performed with SIMPACK, DLR's prime multibody computer code. Results will be presented on using the multi-objective parameter optimization software ANDECS. The design case study will concentrate on taxiing of a flexible aircraft. Reduction of the so-called 'beaming effect' (e.g. dynamic coupling of runway excitation with elastic fuselage eigenmodes) is the major design goal.

LANDING GEAR SHIMMY: DE HAVILLAND'S EXPERIENCE

Glaser, John, De Havilland Aircraft Co. of Canada Ltd., Canada; Hrycko, George, De Havilland Aircraft Co. of Canada Ltd., Canada; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 12p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Landing gear shimmy is an unacceptable situation which, at the very least, leads to increased maintenance costs and at the worst could result in catastrophic failure of the gear and/or the attaching structure. Two landing gear shimmy problems experienced by de Havilland are presented, one in service and the other predicted during design. While these problems occurred over 10 years ago, it is the

authors' contention that little progress has been made in this design discipline in the intervening years. It is recommended that advisory material is needed in this important but often neglected subject.

UNSTEADY TIRE DYNAMICS AND THE APPLICATION THEREOF TO SHIMMY AND LANDING LOAD COMPUTATIONS

Koenig, Klaus, Daimler-Benz Aerospace A.G., Germany; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 10p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

A complete set of nonlinear equations of unsteady tire dynamics for all the 6 degrees of freedom of the wheel movement is presented. The coefficients of these equations are based on available publications and may need some improvements. The influence of some of the coefficients which are new or controversially discussed is shown revealing areas of caution and stressing the necessity of adequate tire tests. Nevertheless it could be demonstrated that reasonable shimmy analyses are possible with these equations and that the computation of realistic unsymmetric landing impacts require their inclusion as a must.

INFLUENCE OF NONLINEARITY ON THE SHIMMY BEHAVIOUR OF LANDING GEAR

Woerner, P., Messier-Dowty S.A., France; Noel, O., Messier-Dowty S.A., France; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 12p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

One of the most critical vibratory phenomena which may occur on a landing gear is called 'shimmy'. It is typically unstable oscillations that could reach such a level of instability that major landing gear structural components may be damaged or destroyed. For many years, Messier-Dowty S.A. has studied this phenomenon in order to perform more accurate predictions of the dynamic behaviour of landing gear. Several models have been developed taking into account many parameters, and especially the non-linear ones, in agreement with test measurements. Simulations have been performed, which show the sensitivity of shimmy stability to variations of these parameters, and therefore the importance of taking account non-linearities in shimmy landing gear models.

A NONLINEAR MODEL FOR LANDING GEAR SHIMMY WITH APPLICATIONS TO THE MCDONNELL DOUGLAS F/A-18A

Baumann, Jeff, McDonnell-Douglas Aerospace, USA; The Design, Qualification and Maintenance of Vibration-Free Landing Gear; Mar. 1996; 12p; In English; See also 19960022102; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

This paper discusses a nonlinear shimmy model that includes components and features typically found in the nose landing gear of fighter aircraft. The gear structural model includes inertia, coulomb and viscous damping, stiffness, and torsional freeplay. Single and dual non-corotating wheels are considered. The tires are represented with the Moreland point-contact tire model. Qualitative analytical results from modeling the nose landing gear of the McDonnell Douglas F/A-18A are presented. This landing gear, in the normal US Navy carrier-based configuration, is stable. When the launch bar and its power unit are removed for land-based versions of the aircraft, the nose gear may, under certain adverse conditions, experience shimmy. This condition can be aggravated by rotating forces due to tire unbalance or other irregularities. A number of corrective modification have been attempted with varying degrees of success. These range from relatively simple measures, such as increasing attention to tire maintenance, to more complicated schemes, such as adding a friction collar, adding mass dampers or even adding a dummy launch bar. For the

most severe cases, the dummy launch bar seems to be required, however, the friction collar with mass dampers does show a significant improvement.

The papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium on 'Aerodynamics of Store Integration and Separation', which was held 24-27 April 1995 in Ankara, Turkey are contained in this report. In addition, a Technical Evaluator's Report aimed at assessing the success of the symposium in meeting its objectives, and an edited transcript of the General Discussion held at the end of the symposium are also included. The aim of this symposium was to bring together engineers in the fields of theoretical and experimental aerodynamics, as applied to the store integration problem, to review and discuss the state of the art in the prediction, methodology and experimental techniques currently being developed and applied to the aerodynamics of store carriage and release and to assess new design concepts.

STRATEGIES FOR MODELLING AERODYNAMIC INTERFERENCE DURING STORE SEPARATION

Deslandes, R., Daimler-Benz Aerospace A.G., Germany; Feb. 1996; 12p; In English; See also 19960022326; Original contains color illustrations; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

All contributions dealing with the modelling of aerodynamic interference of store separation can be catalogued according to their strategies. In the following it will be shown that the great number of available solutions can be reduced to only two categories denominated here Pseudo-Unsteady and Unsteady Strategies. Pseudo-Unsteady Strategies are the most common solutions applied to industrial projects. The three powerful variants are identified as Decay Factorization, Flow Angularity and Iterative Techniques. This last subcategory provides the link between pseudo- and real-unsteady approaches, which are divided into two main groups of strategies, assigned to Global Solutions and Grid-Overlapping Techniques. In addition to this catalogue, the common computational fluid dynamical tools of store separation are outlined respective to their physical relevance and their numerical complexity. Finally an example based on consideration of three strategies, in use at Daimler-Benz Aerospace AG (DASA) will be demonstrated.

The principle of the local incidence methods used by Aerospatiale Missiles for the studies of 'letting go' is presented. Their limits are accordingly evidenced. For this reason, they are completed by numerical simulation, based on solving Euler equations, of the flow around the aerodynamic missile configuration. The principle difficulty in calculations of this type is creating the computational grids. The

Chimera approach is used for modeling. The principle of the first method that will be developed here, called the Chimera Method by Recovery (MCR -- french acronym), is recalled. It widely inspired those used by Benek et al.. It is used for simulating the ASMP missile release under a Mirage 2000. However, the problems become apparent when the missile is in position to take-off, where it is very close to the aircraft. This is why a new method, called Chimera Method by Truncation (MCT) is developed. Its principle is exposed, with care to distinguish it from MCR. It equally has inconveniences. A third method, called Chimera Mixed Method (MCM), is created. It blends the MCR and the MCT, the combination preserving the advantages of each method. The MCT is validated in a 2D case. The study of a 3D configuration, which can represent a missile in release position, shows that the MCM gives much better results than those obtained with MCR.

Ejection as a firing mode for new missiles developed by Matra Defense created a need for new developments in the simulation of the store aerodynamic behavior during the separation phase. We present here four methods used in the separation predictions, on one hand methods based on an experimental approach in wind tunnel: captive trajectories and grids, and on the other hand computational methods: 'local flow incidence' method and Chimera method.

THEORETICAL PREDICTION OF STORE RELEASE TRAJECTORY USING THE FAME METHOD

Blaylock, T. A., Defence Research Agency, Farnborough, UK; Feb. 1996; 10p; In English; See also 19960022326; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

A method is described for generating surface and field meshes around complex configurations. The method, known as FAME (Feature-Associated Mesh Embedding) combines a high degree of automation and ease of use with precise control over mesh quality. The extension of the method to deal with configurations with components in relative motion is described. Euler flow results, at a transonic Mach number and at two different angles of incidence, are presented for a store released from a cluster of three beneath a wing.

**DEVELOPMENT OF NUFA AND ITS APPLICATION WITHIN A
HYBRID STORE LOAD PREDICTION METHOD**

McDougall, S., British Aerospace Public Ltd. Co., UK; Press, A. J., British Aerospace Public Ltd. Co., UK; Feb. 1996; 20p; In English; See also 19960022326; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The NUFA semi-empirical prediction program was originally developed to estimate the aerodynamic loads experienced by configurations immersed in a non-uniform flowfield such as those found in close proximity to a parent aircraft. The code is used throughout BAe Defence Ltd. for the prediction of isolated weapon aerodynamic loads and the determination of carriage/trajectory characteristics both in a stand-alone mode and integrated into trajectory calculation suites. A recent new release of the program incorporates a number of develop-

ments aimed at extending the range of configurations which can be modelled, improving the accuracy of existing calculation techniques and improving the user/program interface. Additionally, development work is currently being carried out to enable the modelling of stores with bodies of arbitrary cross-section with the aim of allowing the program to estimate the loads experienced on modern configurations developed for improved low observability and submunition dispensing purposes. An outline description of the new capabilities which have been incorporated into the current release version of the program and those which are still undergoing development is given within this paper. The code has undergone extensive validation studies for the estimation of free-air store characteristics and the determination of carriage/grid loads within a hybrid load prediction scheme. The hybrid scheme requires the flowfield in which the store is immersed to be input to NUFA. The flexibility of the scheme is such that the flowfield may be obtained from any source, either experiment or theoretical method. Examples of the use of the hybrid scheme are presented, demonstrating the flexibility, relatively low cost and ease of use of the technique.

ENGINEERING-LEVEL METHODS FOR CARRIAGE LOADS, HIGH ALPHA LAUNCH FROM PITCHING AIRCRAFT, AND SUBMUNITION AERODYNAMICS

Dillenius, Mamix F. E., Nielsen Engineering and Research, Inc., USA; Perkins, Stanley C., Jr., Nielsen Engineering and Research, Inc., USA; Lesieutre, Daniel J., Nielsen Engineering and Research, Inc., USA; Feb. 1996; 10p; In English; See also 19960022326; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Recent applications are presented of engineering-level methods to describe or predict store carriage and separation problems. The examples described in this paper are concerned with estimating aerodynamic load acting on the tail fins of a wing-tip mounted missile, predicting trajectory characteristics of a stable and a less stable missile rail-launched from a pitching aircraft at high angle of attack, and predicting aerodynamic aspect of submunitions in the vicinity of a dispenser. In most cases, comparisons with experimental data are shown. The engineering-level approaches are capable of handling parametric studies involving store component loads and store separation from a maneuvering aircraft and the methodology can predict submunition aerodynamics quickly. The particular store separation problems described herein are not easily accomplished with the more accurate CFD approaches especially for cases involving maneuvering parent aircraft.

Pegasus(R), the air-launched space booster designed for launch from B-52 and L-1011 aircraft, was developed using computational aerodynamic methods without benefit of specific wind tunnel or flight testing. This paper describes the methods and procedures used for predicting the carriage and launch characteristics of Pegasus from both B-52 and L-1011 aircraft. Flight data from four B-52 launches and a single L-1011 launch are available to validate the prediction methods.

The capabilities of a six degree of freedom Captive Trajectory System (CTS) in a transonic wind tunnel are investigated, and some aspects related to its operation are singled out. The two operative modes ('position' mode and 'velocity' mode) and the repeatability of the data under those conditions expected to be critical are analyzed. The capabilities of the facility, are studied by means of a test campaign with a typical interference geometry, composed of a store and a wing-fuselage aircraft. The results obtained show that the CTS technique can simulate the effect of the various parameters affecting the trajectory of a released store, within the usual limitations of a wind tunnel simulation. With the CTS technique, the analysis of several different parameters proved easy and fast to carry out. Furthermore, a 'grid test' performed on the same configuration underlined the importance of this application of the CTS for a better understanding of the aerodynamic behaviour of the interfering bodies, which appears to be an essential feature for correctly defining safe and efficient conditions for store release.

This paper will discuss wind-tunnel testing aspects of store trajectory modelling and store carriage load evaluation, at small scale, in the British Aerospace, Military Aircraft Division, (M.A.D.) wind-tunnel facilities. There is discussion of the enhancements, developed within the department, of the 'light model' scaling technique for free store wind-tunnel releases, and of the recent re-appraisal of strain gauge balance design philosophy and the use of newer concepts in strain measurement in small, stiff, balance structures, which is building on our expertise in this field.

A Canadian Forces stores separation prediction capability was initiated in the late 1970s with the development of a store separation computer model supported by wind tunnel measurements. The separation of an external store from an aircraft is a complex event requiring, among other items, a detailed knowledge of the influence of the aircraft flowfield upon the store. The grid survey method, which is essentially a flowfield mapping technique, offers an accurate method for acquiring aerodynamic interference coefficients which are input to the store separation model. However, due to small model scales used for grid survey measurements, additional larger scale wind tunnel investigations are often necessary in order to ensure a faithful reproduction of the store model.

ESTIMATION OF STORE INTERFERENCE LOADS USING TRANSONIC SMALL DISTURBANCE THEORY AND INFLUENCE FUNCTION METHOD

Piperni, P., Bombardier, Inc., Canada; Stokoe, K., Bombardier, Inc., Canada; Feb. 1996; 12p; In English; See also 19960022326; Original contains color illustrations; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper presents a method for predicting aerodynamic interference loads on stores which are ejected or launched from the CF-18 aircraft at transonic flight conditions. A transonic small disturbance theory and an influence function method were employed to estimate interference loads. Predictions for the AIM-7 sparrow missile in the presence of a 330 gallon fuel tank on the aircraft centerline and 980 gallon fuel tanks on the inboard wing pylons are compared with wind tunnel test results. Corrections for sting effects are also included.

FLIGHT TEST TECHNIQUES FOR WEAPON/STORE RELEASE TRAJECTORY ANALYSIS

Donaldson, T., British Aerospace Defence Ltd., UK; Gill, A. D., British Aerospace Defence Ltd., UK; Feb. 1996; 8p; In English; See also 19960022326; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The use of store trajectory prediction techniques is an integral part of a stores release clearance program. In support of these prediction techniques, it is necessary to produce a highly accurate measured trajectory from the flight trial demonstrations. The procedure used at Warton is based on a mathematical model and a fly - match - fly progression and this paper identifies the techniques used by British Aerospace Warton to calculate the store release trajectories. It identifies the store trajectory analysis system that is currently in use and the system enhancements, which includes an automatic tracking facility, that are being introduced. The aim of the system upgrade is to produce more accurate trajectories in reduced timescales and hence reduce the number of flights and store releases required. This will lead on to a reduction in costs and shorter trials programs. The paper also identifies future system enhancements that can be introduced that may lead to the advent of real time store trajectory analysis.

THE IMPLICATIONS OF STORES CARRIAGE AND RELEASE FOR AIRCRAFT FLIGHT CONTROL SYSTEM DESIGN

Allen, D. A., British Aerospace Defence Ltd., UK; Hulme, K. F., British Aerospace Defence Ltd., UK; Feb. 1996; 12p; In English; See also 19960022326; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Against a backdrop of a review of the capabilities and limitations of a modern digital aircraft flight control system, this paper considers the implications of the carriage and release of a wide range of stores for modern high performance military aircraft. At the heart of any flight control system design is consideration of the characteristics of the vehicle and its operating environment. It is in consideration of these aspects that the major impact of external (and internal) stores carriage and release occurs. The relevant vehicle characteristics are described by its aerodynamic, inertial, and structural properties which are all complex in their own right but are also substantially affected by stores carriage. Releasing stores from the vehicle will excite both rigid body and flexible modes of the vehicle due to rapidly changing the vehicle's mass, inertial and aerodynamic characteristics. Despite the rapid technological advances in flight control system design, the underlying physical limits remain, and will continue to do so! A clear recognition of these limitations and their implications is essential, particularly at the concept and early design stages of a project. This paper addresses the major issues involved and the interaction between stores integration and flight control system design for modern fighter aircraft.

The members of AGARD FMP Working Group 21, representing aircraft manufacturers, research institutions and operational organizations, met over a two year period, 1993-1995 to address the following objective: Summarize the status of current cockpits, highlight their benefits and weaknesses, and provide guidance for future cockpit design. This report, the result of those meetings, is structured around the series of questions listed below: (1) What are the pilot and crew required to do to complete a mission successfully; (2a) What do the current glass cockpits consist of; (2b) What are some of the technological highlights and trends of these cockpits; (3) What new technologies are becoming available; (4) How can we tailor the cockpit to be the most suitable for the human operator; (5) How can and how does the use of glass cockpits change the required aircrew training process; (6) What are the key problem issues with the current design process and what suggestions can be made to improve it and; (7) What are the cockpit concepts being considered to improve the operational effectiveness of future aircraft. With consideration of the human factors issues in design as a major basis for this report, this document provides an in depth discussion of the cockpit of today's aircraft and can serve as a foundation upon which to develop a more optimized pilot-vehicle-system interface of tomorrow.

Major trends in technology, weapon system performance goals and affordability for aerospace systems are occurring simultaneously. For avionics systems this performance and affordability can be achieved by functional and physical integration. 'Functionally' integrated subsystems to achieve higher performance has been greatly aided by advances in computer technology. The desire to minimize costs for these systems has been accomplished through a 'physical' integration concept based upon common modules tied through a high speed backplane. The concept, called integrated avionics, has been used on new aircraft such as the US Air Force F-22 fighter and the Boeing 777 commercial transport. Vehicle management systems provide the management of crucial flight functions and systems for advanced aerospace vehicles. These systems must have high integrity, safety, and overall fault tolerance. Low cost modular avionics are unproven for such fault tolerant systems. This becomes a key issue for investigation. This report deals with the key problems in fault tolerance for modular computer based systems. New techniques, only recently applied, provide exciting possibilities to reduce avionics costs and maintain high integrity and safety. These techniques and more are discussed in this report sponsored by the Mission Systems Panel of the AGARD.

EVALUATION OF LOADS FROM OPERATIONAL FLIGHT MANEUVERS
 Apr. 1996; 124p; In English
 Report No.(s): AGARD-AR-340; Copyright Waived; Avail: CASI; A06, Hardcopy; A02, Microfiche

This AGARD Advisory Report describes an evaluation of a method to derive loads from operational flight maneuvers. The basic assumption of this method is that all operational maneuvers performed in service can be verified as a set of Standard Maneuvers (normalized parameter time histories for each independent maneuver type). The verification of Standard Maneuvers is based on recordings of relevant maneuver parameters in service and for new tactics/missions on special flights or simulations. The initial evaluation of the concept done by the Working Group (WG.27) has demonstrated the feasibility of determining loads from operational flight maneuvers.

F., National Research Council of Canada, Canada; Sun, Y., National Research Council of Canada, Canada; Progress and Challenges in CFD Methods and Algorithms; Apr. 1996; 12p; In English; See also 19960053167; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

With the high costs associated with flight and wind tunnel testing, the computation of aircraft store trajectories is becoming more important to the military establishment. In Canada, the Department of National Defense (DND) requested IAR to acquire/develop the necessary tools to carry out the prediction of stores on release from aircraft - particularly the DND's CF-18 aircraft. After debating whether to use structured Chimera schemes or unstructured schemes, IAR decided to use the latter techniques as there was already a development program in that field of research. IAR had already demonstrated that hybrid (structured/unstructured) grids had produced successful results and decided to pursue this approach for the unsteady 3D

computations. To this end, a study was made in the 2D case of a 'store' moving from the parent 'body'. Grid generation is underway for the full CF-18 aircraft using a commercial code and several simpler cases have been gridded and computations made in a steady 3D environment.

PROPULSION INTEGRATION ASPECTS IN ADVANCED MILITARY AIRCRAFT

Hienz, E., Eurofighter Jagdflugzeug G.m.b.H., Germany; Illuzzi, L., Eurofighter Jagdflugzeug G.m.b.H., Germany; Herrmann, P., Eurojet Turbo G.m.b.H., Germany; Advanced Aero-Engine Concepts and Controls; Jun. 1996; 18p; In English; See also 19960054418; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Historically, airframe/engine integration was mainly related to physical aspects requiring only a low degree of sophistication. With the advent of more overall system performance consciousness, propulsion integration has become a major task split between airframe and engine engineers. It now includes performance, functional and physical aspects all needing to be integrated to meet specific requirements. Aircraft and engine configurations are therefore optimized simultaneously at a very early stage of development. Some of the major interfaces influencing configuration, performance, and operability are discussed, i.e., intake/engine/afterbody; and electronic controls integration (including monitoring); performance optimization, systems, and installation.

UK ATTACK HELICOPTER FLYING QUALITIES: THE ROLE OF PILOTED SIMULATION EVALUATION IN SUPPORTING THE PROCUREMENT DECISION MAKING PROCESS
 Charlton, M. T., Defence Research Agency, UK; Padfield, G. D., Defence Research Agency, UK; Green, J. T., Ministry of Defence, UK; Apr. 1996; 20p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Contenders for the UK Army's Attack Helicopter (AH) competition, were subjected to a Technical Assessment during the period November 1993 to December 1994. The Defence Research Agency's Flight Dynamics and Simulation Department were Lead Assessors for the flight control system and handling qualities aspects of the assessments. FDS carried out a program of off-line and piloted simulation activities in support of the handling qualities assessments, using the DRA's HELISIM simulation model. A piloted simulation evaluation was completed using the DRA's Advanced Flight Simulator, where the objective was to evaluate the contenders handling qualities and agility in the context of the AH mission. The paper describes the test techniques and procedures used in the tests and discusses the background details of the handling qualities assessment methodology. Some conclusions are also drawn regarding the effectiveness of simulation in supporting defence procurement objectives, and potential future developments.

THE USE OF PILOTED SIMULATION FOR CIVIL TILTROTOR INTEGRATED COCKPIT DESIGN

Decker, William A., NASA Ames Research Center, USA; Simmons, Rickey C., NASA Ames Research Center, USA; Tucker, George E., NASA Ames Research Center, USA; Apr. 1996; 24p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Ground-based flight simulators are receiving increased use in the design of civil aircraft. In addition to traditional simulation roles in support of cockpit control and display design, simulators are now used

to develop new flight procedures and to assist in airport design. This is particularly true for the concept of a civil tiltrotor transport. This presentation summarizes recent simulation activity at NASA's Ames Research Center focused on the design requirements for the introduction of tiltrotor aircraft as economic vertical flight transports.

SIMULATION APPLICATIONS IN V-22 AND RAH-66 DESIGN AND DEVELOPMENT

Sheffield, R. E., Boeing Defense and Space Group, USA; Lalicker, L. E., Boeing Defense and Space Group, USA; Apr. 1996; 6p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The Boeing Company Defense & Space Group, Helicopters Division, has increasingly applied constructive and virtual simulation in support of its aircraft developmental programs which include the V-22 Osprey and the RAH-66 Comanche. From their conceptual phases to present, methodologies and mission simulation capabilities have evolved rapidly due to tremendous advances in computing power. By interacting directly with the systems engineering process, simulation has proven to be extremely valuable in optimizing rotorcraft survivability and mission effectiveness. At the same time, simulation has proven to be an effective means of reducing risk and costly flight testing. Recent focus has been on evolving our simulation capabilities for participation in Distributive Interactive Simulation (DIS). These capabilities and their acquired techniques provide potential opportunities to (1) better apply simulation to increase operational effectiveness of future rotorcraft, and (2) facilitate customer involvement in the developmental process.

PILOTED SIMULATION IN ROTORCRAFT DESIGN AND DEVELOPMENT: EUROCOPTER EXPERIENCE AND FUTURE TRENDS LA SIMULATION PILOTEE POUR LA CONCEPTION ET LE DEVELOPPEMENT DES APPAREILS A VOILURE TOURNANTES: L'EXPERIENCE D'EUROCOPTER ET LES TENDANCES POUR LE FUTUR

Rollet, Philippe, Eurocopter France, France; Apr. 1996; 10p; In French; See also 19970000594; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Piloted simulation has largely been used in EUROCOPTER's developments for the last 10 years. For the TIGER attack helicopter, piloted simulation was extensively used from the very beginning of the development to the prototypes' nights. Today, the development of the NH-90 helicopter requires a lot of experimentations on the SPHERE simulator. Piloted simulation is also used for research related to handling qualities, such as the ACT European program, or to Man-Machine-Interfaces (MMI's). The implementation of demonstrators, such as the FBW DAUPHIN, as well as the study of the EUROFAR Tilt-Rotor have also largely involved piloted simulations. A significant experience in testing procedures has been acquired. Environmental and human factors appear to be of the greatest importance. In the future, evolutions are planned to further enhance the representativity of SPHERE simulator. The emergence of new design standards, such as ADS-33C, leads to envisage new applications of piloted simulation.

RESEARCH APPLICATIONS AND CAPABILITIES OF THE NASA/ ARMY ROTORCRAFT AIRCREW SYSTEMS CONCEPTS AIRBORNE LABORATORY (RASCAL)

Aiken, Edwin W., NASA Ames Research Center, USA; Jacobsen, Robert A., NASA Ames Research Center, USA; Hindson, William S., NASA Ames Research Center, USA; Apr. 1996; 14p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The Rotorcraft Aircrew Systems Concepts Airborne Laboratory (RASCAL) is a UH-60 Black Hawk helicopter that is being modified by NASA and the US Army for flight systems research. The principal systems that are being installed in the aircraft are a Helmet-Mounted Display (HMD) and associated imaging systems, and a programmable full-authority Research Flight Control System (RFCS). In addition, comprehensive instrumentation of both the rigid body of the helicopter and the rotor system is provided. This paper describes the design features of this modern rotorcraft in-flight simulation facility and their current state of development. A brief description of initial research applications is included.

FUNDAMENTALS ON DAMAGE MONITORING

Boller, Christian, Daimler-Benz Aerospace A.G., Germany; Oct. 1996; 16p; In English; See also 19970001697; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Within the paper, the following is discussed: existing load monitoring systems in aircraft and their use for fatigue damage evaluation; validation of different NDT-techniques with regard to their use for and integration into composite materials; validation of the use of structural health (damage) monitoring systems; parameters and techniques based on piezoelectric sensing for monitoring impact loads. It is concluded that structural health monitoring can have a beneficial effect in combination with composite materials.

Since the late fifties when fatigue problems in aircraft structures were first encountered, aircraft maintenance has evolved through research, and subsequent implementation in well-orchestrated programs in several NATO countries. In the USA Air Force, the Aircraft Structural Integrity Program (ASIP), and similar programs in other US service organizations, deserve much of the credit for establishing a first class record for US fleet readiness. ASIP's success, similar to other NATO programs, rely heavily (still) on frequent aircraft inspections to ensure fatigue cracking, or other flaws, get the necessary attention, and appropriate corrective action, before vehicle safety is compromised. Recent initiatives at Northrop Grumman, together with research elsewhere in structural health monitoring systems (SHMS), now point one step further toward improved safety and maintenance costs reductions. Though not yet mature, recent technological advances in sensors, data acquisition, electronic miniaturization, and sensor system integration, now make it conceivable, at least, to replace current scheduled driven inspection practices - prevalent in aerospace systems maintenance throughout NATO- with 'maintenance-on-demand.' Put simply, aircraft structural inspections and maintenance will be performed only when really necessary and there is a high probability of finding damage, rather than scheduled, when often there is no damage detected. An overview of ASIP is first introduced as background to the subject of structural health monitoring in the US reviewing inspection requirements, critical flaw sizes, and operational load environments. SHMS technologies are subsequently reviewed featuring requirements, architectures and components, sensors, processors, analysis algorithms and software, and SHMS component technology status. Finally, conclusions and recommendations for technology transition and future work are reported.

ADAPTIVE AIRCRAFT WING

Kudva, Jayanth N., Northrop Grumman Corp., USA; Lockyer, Allen J., Northrop Grumman Corp., USA; Appa, Kari, Northrop Grumman Corp., USA; Oct. 1996; 6p; In English; See also 19970001697; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The concept of an adaptive aircraft wing, i.e., whose shape parameters such as camber, span-wise twist, and thickness can be varied to optimize the wing shape for various flight conditions, has been extensively studied by numerous researchers. While the aerodynamic benefits (in terms of increased lift/drag ratios, improved maneuverability, and delayed flow separation) have been analytically and experimentally established, the complexity and weight penalty of the designs and actuation mechanisms have limited their practical implementation. Recent developments in sensors and actuators using smart materials could potentially alleviate the shortcomings of prior designs, leading the way to a more practical 'smart' adaptive wing which responds to changes in flight and environmental conditions by optimally modifying its shape. A summary of recent work in the area of adaptive wing concepts incorporating smart structures technologies is presented. Emphasis is placed on continuing research at Northrop Grumman under a USA Defense Advanced Research Projects Agency (DARPA) contract entitled 'Smart Structures and Materials Development-Smart Wing.' Limitations and potential benefits of adaptive wing designs, applications and advantages of smart material actuators and sensors, and results of recent tests are discussed. Recommendations for future work required to develop an operational smart adaptive wing are also outlined.

COMPUTATIONAL MODELING AND VALIDATION FOR HYPERSONIC INLETS

Povinelli, Louis A., NASA Lewis Research Center, USA; Aerothermodynamics and Propulsion Integration for Hypersonic Vehicles; Oct. 1996; 10p; In English; See also 19970009247; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Hypersonic inlet research activity at NASA is reviewed. The basis for the paper is the experimental tests performed with three inlets: the NASA Lewis Research Center Mach 5, the McDonnell Douglas Mach 12, and the NASA Langley Mach 18. Both three-dimensional PNS and NS codes have been used to compute the flow within the three inlets. Modeling assumptions in the codes involve the turbulence model, the nature of the boundary layer, shock wave-boundary layer interaction, and the flow spilled to the outside of the inlet. Use of the codes and the experimental data are helping to develop a clearer understanding of the inlet flow physics and to focus on the modeling improvements required in order to arrive at validated codes.

INTEGRATED AIRFRAME DESIGN TECHNOLOGY LES TECHNOLOGIES DE LA CONCEPTION INTEGREE DES CELLULES

Integrated Airframe Design Technology; Oct. 1996; 174p; In English; In French; 82nd; Structures and Materials Panel, 8-9 May 1996, Sesimbra, Portugal; See also 19970010667 through 19970010680 Report No.(s): AGARD-R-814; ISBN 92-836-0030-4; Copyright Waived; Avail: CASI; A08, Hardcopy; A02, Microfiche

Integrated airframe design embraces the concept of bringing together all of the aspects of airframe design, including various disciplines such as structures, materials, aerodynamics, propulsion, systems, controls, and manufacturing from conceptual design all the way through to the final product and its repair and maintenance. The results of this AGARD Workshop on Integrated Airframe Design emphasized that the recent and future advances in high-performance

computer hardware and software systems provide the opportunity to create a process that will allow these disciplines to rapidly interact with one another.

Design for affordability is the new paradigm for the 21st Century. Balancing the conflicting goals of systems superiority and systems affordability is the challenge of multidisciplinary design optimization on a larger scale than has ever been done before. Addressing the realities of the future aerospace business has led to a new vocabulary. Northrop Grumman pioneered many of these concepts on the B-2 Program during the 1980's. Since then we have taken the lessons learned, coupled with commercial off the shelf software and integrated them into formal protocols for affordable aircraft production, resulting in a Toolbox for Affordable Production.

Airframe product design integration is continuously evolving with the goal of facilitating the design team's mission; development of 'build-to' datasets that provide the complete definition of hardware to be manufactured. This paper surveys design tools, practices, and strategies in Lockheed Martin Tactical Aircraft System's (LMTAS) integrated environment. Airframe design is a set of structured and chaotic processes coordinated to establish product function and fit, affordability, producibility, and structural certification. Integration encompasses the data development, data transfer, and knowledge development necessary to create the product. Evolution of integrated design at LMTAS is resulting from influx of advanced technologies such as scientific visualization, multidisciplinary analysis and optimization, and data exchange standards. Illustrations of advanced technologies and their implementation at Lockheed Martin Tactical Aircraft Systems are provided in the context of conceptual design, preliminary design and detailed design. New aircraft design programs offer opportunities.

A COMMON FRAMEWORK ARCHITECTURE FOR AN INTEGRATED AIRCRAFT DESIGN

Krammer, J., Daimler-Benz Aerospace A.G., Germany; Vilsmeier, J., Daimler-Benz Aerospace A.G., Germany; Schuhmacher, G., Siegen Univ., Germany; Weber, C., Siegen Univ., Germany; Oct. 1996; 10p; In English; See also 19970010666; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The paper first describes the architecture of the framework and the processes which are implemented. After that the concept of a common optimization model formulation based on the design element method and its integration in the overall process is explained. As an example for the so-called 'constructive design model' the optimal layout of a stiffened panel under buckling loads is considered.

Multi-disciplinary Design Optimization (MDO) requires sensitivities and model data to be handled among many applications, such as FE and CFD codes. Each iteration to the optimum design requires a re-execution of some of the applications, presenting a new input data and receiving updated sensitivities. All this takes place within applications moving from a central mainframe to numerous UNIX workstations. Therefore, in order to perform MDO one has to solve problems of transferring data and executing remote applications. Most applications are to be available during a lengthy optimization process, which affects the reliability of networks and computers. This paper will outline our vision of MDO and detail our work and problems in performing: remote application execution; data transfer over local and wide networks; network topology to give redundant data paths; redundant computers via multiple application installations; real-time interactive guidance of the optimization process; and dynamically linking distributed applications to parallelize the optimization process across workstations and supercomputers.

We present the process of drawing-analysis interactions for airframes design, based on the capabilities of our coupled CAD analysis tools CATIA and ELFINI: (1) for preliminary project, global definition of airframe by CATIA objects associated with a global Finite Element model and with a mathematical optimization of the dimensioning; many, fast and cheap evaluations of alternate architectures are possible; and (2) for development phase, detail drawings of parts with CAD 'solid' models, lay-out studies with a digital mock-up, verifications by non linear finite element analyses or by partial tests; the present difficulty of the process restricts design iterations. Due to limitations of numerical means and of partial tests, the demonstration of structure qualification must be jointly founded on general tests (flight tests, static test airframe). Prospects of tool development are revoked: multidisciplinary and multilevel optimizations, availability of repeatable Design Historical Records, Feature Modeling generalized to analyses and to optimization. These tools will provide more means for iterations at every project stage, they allow to fully master costs, time and risks in project development phases; yet they present the problem of preservation of innovation capability with the full standardization of designs and processes.

An automated and integrated structural design and analysis process for aircraft and weapons airframes is described. The primary purpose of the process is to reduce design cycle time and to tie structural design and performance to 'design to cost' analyses. This capability is included in a general system, called the Affordable Systems Optimization Process (ASOP), which includes five separate, but linked systems: The 'Design to Cost' Tool, Automated Structural Analysis Process (ASAP), an ultra rapid finite element model generator and transformation pre/post processor (COMETRAN), Active Aeroelastic Wing Optimizer (AAW), and CFD based static and dynamic aeroelasticity (ENSAERO). This evolving system has already significantly reduced structural design cycle time, and is being expanded to include more design disciplines.

A SIMPLIFIED APPROACH TO THE MULTIDISCIPLINARY DESIGN OPTIMIZATION FOR LARGE AIRCRAFT STRUCTURES

Morell, Miguel Angel, Construcciones Aeronauticas S.A., Spain; Huertas, Manuel, Construcciones Aeronauticas S.A., Spain; Gomez, Jose Carlos, Construcciones Aeronauticas S.A., Spain; Oct. 1996; 12p; In English; See also 19970010666; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The last tendencies in optimization indicate that in early design stages, it is necessary to perform multidisciplinary analysis for designing large structures. This paper presents a simple but very efficient tool that CASA is using during the preliminary stages of the aircraft structural design for defining and selecting the structural characteristics. The development of this software package, ALACA, was undertaken by CASA Engineering Directorate in the last years for the purpose of designing the composite wing of CASA 3000 Aircraft. ALACA optimizes wing structures satisfying all the structural requirements (weights, static loading, material, fatigue, residual strength, manufacturing, flutter, etc.). The main advantage of the program is that it is not necessary to use finite element techniques, which make it easier than other available codes and allows to use it in the earliest phases of the project (preliminary design) before freezing the general arrangement of the structure. The results from the CASA 3000 studies show the reliability and efficiency of ALACA as a design tool.

MONTE CARLO-BASED STOCHASTIC FINITE ELEMENT METHOD: A NEW APPROACH FOR STRUCTURAL DESIGN

vanVincenroy, G., Vrije Univ., Belgium; deWilde, W. P., Vrije Univ., Belgium; Vantomme, J., Royal Military Academy, Belgium; Oct. 1996; 12p; In English; See also 19970010666; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The paper summarizes the principles of the Monte Carlo based finite element method. The method relies on the characterization, by means of stochastic tools, of the mechanical behavior of different materials with uncertainties taken into account. A procedure based on the combination of three methods for estimating distribution parameters has been set up to ensure a correct estimation of the material properties that are used as input for the finite element model. The stochastic engineering design method is then applied to beam structures. Although the present report is limited to the linear analysis, it is concluded that attention should be paid to the Monte Carlo sample size required to obtain accurate results and to the appropriate choice of the finite element mesh to avoid excessive CPU time consumption and errors in the interpretation of the results.

THE GAS TURBINE ENGINE CONCEPTUAL DESIGN PROCESS: AN INTEGRATED APPROACH

Stricker, Jeffrey M., Wright Lab., USA; Oct. 1996; 7p; In English; See also 19970010666; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The conceptual design of gas turbine engines is a complex process which crosses many engineering disciplines. Aerodynamics, thermodynamics, heat transfer, materials design/selection, and structural analysis are a few of the fields employed when downselecting an appropriate engine configuration. Because of the complexity involved, it is critical to have a process which narrows engine options without missing the 'optimum' engine design. The following paper will describe a typical process used at the conceptual design level. Various steps which will be described include propulsion requirements definition, uninstalled engine cycle performance, component design, engine flowpath/weight prediction, installation effects, and the influence of engine design trades on aircraft size and performance. The engine design process is not completely linear. The steps listed above are highly interdependent. A number of iterations are usually necessary in selecting a final engine design. This paper will describe several of the interrelationships between the various steps. Frequently, the engine conceptual design process has special considerations which require additional engine analyses. Some modern day examples of these criteria include reduced observables and cost reduction. How these variations are incorporated into the conceptual design process will be discussed.

One important question in analysis and design is how much error (e(sub N)) has the solution (x(sub N))? The answer is very difficult even if limited strictly to the computation. For two decades the author has researched and developed a Procedure in the University and the INTA to give an answer acceptable to industry. This paper gives the Fundamentals and Applications to two Aerospace Projects: (1) Airplane: C(sub L alpha) (C(sub L) slope); and (2) Satellite: lambda(sub min) (min eigenvalue) whose solutions (x) are unknown, but they can be computed as shown.

THE DYNAMIC RESPONSE OF A TWIN-ENGINE, COMMERCIAL JET TRANSPORT TO WAKE VORTEX ENCOUNTERS

Vasatka, James, Boeing Commercial Airplane Co., USA; Nov. 1996; 12p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

In order to refine existing wake-vortex separation distances through the application of technology, the issues associated with defining the basis for separation criteria must be addressed. This includes understanding the significance of a wake vortex encounter. The results from this study suggest that the airplane's response is dependent on the flight path through the wake.

ON THE INTERACTION BETWEEN TOPOGRAPHICAL WIND AND LANDING AIRCRAFT

Kubberud, Nils, CFD Norway A/S, Norway; Oye, Ivar, CFD Norway A/S, Norway; Norstrud, Helge, Norwegian Univ. of Science and Technology, Norway; Nov. 1996; 12p; In English; See also 19970014096; Original contains color illustrations; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The present paper gives a qualitative study of the flow interaction between a representative landing aircraft and the wind induced vortical flow. Separate numerical analysis for the wind flow over the given terrain and the flow structure around the lifting airplane is given. The interaction is performed by superposing the two solutions in various crossflow planes along the glide path direction of the aircraft. This leads to an estimate of the change of circulation for the lifting body and the associated need for corrective control forces.

Many migrating bird species fly in regular V-shaped formations. Each wing experiences an upwash field generated by all other wings in the formation and this leads to a reduction in flight power demand for each wing as well as for the whole formation. In this paper the aerodynamic interference is studied by means of aerodynamic theory. The total energy saving for the whole formation increases with the number of wings and with decreasing lateral distance. Local power reductions are highest in the inner parts of a formation and they decrease towards the apex and the side-edges. The technical realization of this principle is analysed for two airplanes. In calibration flights of gliders large distances have to be kept or the aerodynamic interference has to be taken into account. In formation flights of two airplanes a power reduction of 15% is obtainable for the rear airplane flying close to the wake of the front aircraft. The corresponding aileron and rudder deflections for compensation of the corresponding moments are small. Flight tests with two airplanes Do-28 show that the power reduction can be achieved in practical flight. The results are in excellent agreement with aerodynamic theory. In order to enable the rear airplane to find the proper position relative to the wake of the front airplane an automatic control system has been adapted. A formation flight controller has been designed which leads the upwash in the symmetry plane and the aileron deflections to maximum values. The application of this control system led to a considerable relief of the pilot and important power reductions could be achieved automatically.

ON THE DYNAMICS OF ENGINE JETS BEHIND A TRANSPORT AIRCRAFT

Jacquin, L., Office National d'Etudes et de Recherches Aerospatiales, France; Garnier, F., Office National d'Etudes et de Recherches Aerospatiales, France; The Characterisation and Modification of Wakes from Lifting Vehicles in Fluids; Nov. 1996; 8p; In English; See also 19970014096; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The various mechanisms that contribute to the mixing and dispersion of the engine exhausts through their interaction with the vortex wake of an aircraft are discussed. The case of a typical large transport aircraft is considered. First, the interaction between the jets and the vortices is characterized by means of non dimensional parameters. When considering aircraft under cruise conditions, it is shown the jets have almost no effect on the vortex wake dynamics. We then consider the way the jet is changed by the vortices. This is evaluated by means of an integral model. Examples are given which show that the jet is captured by the vortices at very different distances behind the aircraft depending on the engine-wingtip separation. The model does not take into account the distortion of the jet plume by the vortex shearing which becomes significant when the jet reaches the vortex center region. Results of a numerical simulation of the convection-diffusion of a passive scalar field, as well as a visualisation realized during an experiment are presented in order to illustrate this point.

PENGUIN MK2 MOD7 INTEGRATION IN THE SIKORSKY S-70B HELICOPTER INTEGRATION AND LIVE FIRE TESTING
 Sollie, Are Christian, NFT, Norway; Spitz, Steve, Sikorsky Aircraft, USA; Nov. 1996; 18p; In English; See also 19970018626; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The paper describes the Penguin MK2 MOD7 (AGM-119B) anti-ship missile integration in the Sikorsky S-70B helicopter. Innovative design techniques allowed use of existing aircraft and missile hardware. Only software development was required to integrate the Penguin missile with the S-70B aircraft. The paper discusses briefly the system integration testing and presents some of the test results. The system integration testing was based on extensive simulation of mathematical models and a low-cost instrumentation of a captive carry flight test range in the Long Island Sound, USA. Finally, some test results from a live firing demonstration performed at USN NAWCAD, Patuxent River are given.

LINEAR STABILITY ANALYSIS OF UNGUIDED MISSILES WITH WRAP-AROUND TAIL FINS IN FREE FLIGHT

Tanrikulu, O., Scientific and Technical Research Council of Turkey, Turkey; Onen, C., Scientific and Technical Research Council of Turkey, Turkey; Mahmutyazicioglu, G., Scientific and Technical Research Council of Turkey, Turkey; Bektas, I., Scientific and Technical Research Council of Turkey, Turkey; Nov. 1996; 13p; In English; See also 19970018626; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A large number of tube launched unguided missiles of NATO such as 70 mm Mk 66, 122 mm FIROS, 127 mm Mk 71, 160 mm RAYO and 227 mm MLRS have wrap-around tail fins (WAF). These missiles have more complicated flight mechanics when compared to the ones with flat and straight tail fins. This is due to the fact that WAF lack mirror symmetry. Detailed free flight mechanics analysis of such missiles were performed with particular emphasis given to the effect of out-of-plane static moment stability derivative $C_{\text{sub m beta}}$ on dynamic stability. In this study, combined effects of $C_{\text{sub m beta}}$ and Magnus moment stability derivative $C_{\text{sub m beta(sub p)}}$ on dynamic stability are explored. Aerodynamics and flight mechanics of a simple configuration with WAF are examined as a case study.

Requirements for the performance of certain NATO missions in the 2015 - 2020 time frame have been examined. In addition, various unmanned aerial vehicle-borne sensor payloads have been identified which support the execution of these missions in an effective manner. Present state-of-the-art sensors and air vehicle systems do not provide the performance necessary to prosecute these missions in light of the anticipated future civil and military environment. This paper presents a discussion of the under-girding technologies which will make the predicted Unmanned Aerial Vehicle (UAV) performance possible. The description of these enabling technologies includes discussions concerning the present state of the art, their general applicability to a variety of UAV payloads, and the collateral technologies which will in turn facilitate the development of the chosen primary enabling technologies. Though a number of enabling technologies have application to the various UAV missions, seven are recommended for near term investment.

The evolution of an automated ship recovery system for a VTOL UAV is discussed. The generic UAV model is based on the Canadair CL227 VTOL UAV. Test results concentrating on system control and response are provided. A description of the data link software and hardware components is presented. The approach describing the location of the air vehicle is based on the decomposition of the state vector into observable and non-observable components. This approach is validated by simulation. The simulation model is based on a six degree-of-freedom representation of the air vehicle, the ship, the data link system and the environment. The data link/recovery system uses vehicle control and ship motion algorithms which close the loop between the air vehicle and ship. Finally, the flight profiles produced by simulation are also discussed.

There is an increase in understanding of the benefits of using UAV's under certain scenarios. Acquisition of operational UAV's for the Turkish military, and lessons learned from recent conflicts in some troubled areas of the world, give impetus to gaining some domestic expertise on the design and operation of drones. Under contract by the Undersecretariat of Defense Industries TAI designed, developed and flight tested two line-of-sight UAV prototypes between 1990-1992. The intent was firstly to demonstrate TAI's design capabilities, and later, to

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

further develop the vehicles into mission capable vehicles by the addition of certain operational functions and mission payloads. The project was successfully completed with the delivery of the vehicles that had limited capabilities. TAI was responsible for the design and development of the airframe, systems integration, and ground and flight tests. Commercially available avionics systems were used in the ground control station and in the aircraft. The project enhanced the in-house knowledge base pertaining to unmanned air vehicles quite significantly, and encouraged the start of further activities that included target drones. Under the contract with MOD, TAI is currently developing a new target drone, TAI-UKHU, for use with the air defense units. In this paper, basically, TAI's efforts will be summarized which cover the UAV-X 1 and the UKHU target drone.

TILTROTOR TRANSPORT BONDED WING DESIGN SUMMARY
Dompka, Robert V., Bell Helicopter Co., USA; Holzwarth, Richard C., Wright Lab., USA; Jan. 1997; 12p; In English; See also 19970019652; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper presents the results of research and development activities conducted under Air Force contract by Bell Helicopter Textron, Inc. (Bell) to apply advanced design and manufacturing technology to reduce production costs of a composite tiltrotor transport vehicle wing. Strength, stiffness, and weight requirements dictated the utilization of advanced composites. This paper will provide a description of the effects of these requirements on wing torque box design and the analysis used to size major structural components and joints. Component verification test results are provided to support the design decisions and validate the analyses and structural integrity. Future plans are presented for a full-scale torque box structural test as demonstration of the viability of the final design.

COOPERATIVE PROGRAMME ON DYNAMIC WIND TUNNEL EXPERIMENTS FOR MANOEUVRING AIRCRAFT PROGRAMME EN COOPERATION SUR L'EXPERIMENTATION DYNAMIQUE EN SOUFFLERIE POUR LA MANOEUVRABILITE DE L'AVION

Oct. 1996; 248p; In English; Original contains color illustrations
Report No.(s): AGARD-AR-305; ISBN 92-836-1043-1; Copyright Waived; Avail: CASI; A11, Hardcopy; A03, Microfiche

This report describes a multinational cooperative program in response to the continuing interest among the NATO countries in dynamic wind tunnel testing. The program consisted of a series of dynamic experiments on models of a schematic combat aircraft configuration and of two generic aircraft forebodies. Ten wind tunnels in seven countries were involved. The dynamic tests included oscillatory, and in one case oscillatory-coning experiments. In several facilities, this was complemented by static and, in some cases, also dynamic flow visualization experiments in water tunnels. The forebody experiments included extensive surface pressure measurements under rotary conditions, carried out in a pressurized wind tunnel. The reliability of current test techniques was examined; and an expanded data base for dynamic data at high angles of attack is presented.

The last half of the twentieth century has seen the rotorcraft come in to prominence as a combat system. Rotorcraft have proven their worth in all environments and in all domains of conflict. They will continue to provide essential military capabilities for the Alliance well into the next century. The objective of this symposium was to capture the current situation in the rapidly changing field of rotorcraft technology. The symposium met its objective. Different parts of this Conference Proceedings should be valuable to anyone currently designing or developing rotorcraft, or doing basic research in rotorcraft technology. Special emphasis in the programme was placed upon the following subjects: (1) the impact of the increasing use of commercial off-the-shelf technology in military helicopter development and use; (2) the increasing acceptance and expanded use of Aeronautical Design Standard ADS-33; and (3) the issue of rotorcraft flight safety. This symposium provided an excellent forum for a varied program of technical presentations. It specifically provided information on the Bell 230, the Tiger, Eurocopter EC 135, the V-22, and the RAH Comanche. The knowledge gained and exchanged at this symposium should assist the attendees in helping to provide NATO with the future affordable combat rotorcraft it will need to maintain our current technological lead.

CERTIFICATION OF MODEL 230 HELICOPTER FOR CATEGORY A ELEVATED HELIPAD OPERATIONS

Goldenberg, Joachim, Textron Bell Helicopter, Canada; Meslin, L., Textron Bell Helicopter, Canada; Blondino, M., Textron Bell Helicopter, USA; Williams, D., Textron Bell Helicopter, USA; Advances In Rotorcraft Technology; Apr. 1997; 10p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

A flight test program leading to the certification of Model 230 helicopter for Category A elevated heliport operations was conducted. This paper discusses the development of the TakeOff and Landing profiles for Transport Helicopters operating from elevated helipads. The development included simulation, ground level helipad tests, and elevated helipad testing. Also presented are the demonstrated helicopter performances for this type of operations. The developed procedures will enable operators to plan for Category A operations from elevated heliports.

THE USE OF SIMULATION TO DEVELOP AN IMPROVED UNDERSTANDING OF HELICOPTER TAIL ROTOR FAILURES AND DEVELOP AIRCREW EMERGENCY ADVICE

Martyn, A. W., Defence Research Agency, UK; Phipps, P., Westland Helicopters Ltd., UK; Mustard, E., Westland Helicopters Ltd., UK; Apr. 1997; 18p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper reviews the use of simulation in recent UK programmes to improve our understanding of helicopter tail rotor failures, and develop the handling advice for aircrew following a tail rotor (TR) malfunction. The paper discusses the original motivation for the work and in particular the research work that has been carried out by the Defence Research Agency (DRA) and Westland Helicopters Ltd (WHL) under UK Ministry of Defence (MOD) funded programmes. This research has included flight trials conducted on the DRA Aeromechanics Lynx Control and Agility Testbed (ALYCAT) to develop Lynx TR control failure handling advice, and simulation trials on the DRA Bedford Advanced Flight Simulator (AFS) to develop Lynx TR drive failure handling advice. The AFS was also used to investigate the influ-

ence of helicopter design parameters on a pilot's ability to recover from a TR failure. Also described are off-line simulation and model development activities. The paper concludes with a review of lessons learnt.

OPTIMAL TRAJECTORIES FOR THE HELICOPTER IN ONE-ENGINE-INOPERATIVE TERMINAL-AREA OPERATIONS

Chen, Robert T. N., NASA Ames Research Center, USA; Zhao, Yi-Yuan, Minnesota Univ., USA; Apr. 1997; 28p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper presents a summary of a series of recent analytical studies conducted to investigate one-engine-inoperative (OEI) optimal control strategies and the associated optimal trajectories for a twin engine helicopter in Category-A terminal-area operations. These studies also examine the associated heliport size requirements and the maximum gross weight capability of the helicopter. Using an eight states, two controls, augmented point-mass model representative of the study helicopter, continued takeoff (CTO), rejected takeoff (RTO), balked landing (BL), and continued landing (CL) are investigated for both vertical-takeoff-and-landing (VTOL) and short-takeoff-and-landing (STOL) terminal-area operations. The formulation of the non-linear optimal control problems with considerations for realistic constraints, solution methods for the two-point boundary-value problem, a new real-time generation method for the optimal OEI trajectories, and the main results of this series of trajectory optimization studies are presented. In particular, a new balanced-weight concept for determining the takeoff decision point for VTOL Category-A operations is proposed, extending the balanced-field length concept used for STOL operations.

The application of fly-by-wire techniques to helicopters allows for a number of advanced control schemes that can be used to enhance performance and safety. An experiment has been carried out in a manned helicopter simulator to evaluate the possibility of making use of such a system to allow the pilot to retain control over the helicopter following catastrophic failure of the lateral cyclic primary control. It was demonstrated that a pilot can switch to pedals as the lateral control input provided that the tail rotor is controlled by an autopilot mode. The feasibility of this process has been evaluated for a range of system configurations and the corresponding handling qualities ratings are reported.

MISSION SIMULATION FOR TIGRE (PROTECTION SUPPORT VERSION) SIMULATION DE MISSION POUR LE TIGRE (VERSION APPUI PROTECTION)

Rigal, J. F., Centre d'Essais en Vol, France; Colas, G., Centre d'Essais en Vol, France; Advances in Rotorcraft Technology; Apr. 1997; 10p; In French; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

As part of the development of the support-protection helicopter version of the TIGRE helicopter, an evaluation of the specifications of the mission system was performed. The prior phases made it possible to tackle aspects pertaining to the crew-system interface, as well as

the symbols and procedures relating to piloting, navigation, and employment of armament, including degraded modes and the integration of specific equipment units into the support-protection version within the basic TIGRE system. This developmental phase made it possible to perform mission simulations, thus ensuring the overall check on the crew workload under conditions as close as possible to real-life missions.

It must be the objective of the army aviation corps flight training to enable helicopter pilots to use their weapon system safely and efficiently by using the technical equipment and possibilities: at day and night, in air mobile combat of combined arms, and under almost all possible weather conditions. This is done in the so-called training equipment compound where the adequate training equipment is assigned to the respective training objective. Partial skills are learned by means of simple procedure trainers and handling models before complex simulators and finally the original device, the helicopter, are used to merge the partial skills. This training equipment compound allows to reduce costs and at the same time to reach those training objectives which will be demanded in the future. Training equipment essentially consists of the following: (1) CBT is an interactive computer based training equipment which is used for interactive learning of flight theoretical and technical aircraft knowledge, navigation training and radio communications. (2) Part Task Trainers are used for hands-on training of partial capabilities. They are corresponding to the respective system in design, layout and operation. (3) Flight Simulators and Combat Mission Simulators will be treated in detail during the further explanations. (4) The close-in combat simulator (AGDUS) corresponds to the common equipment of the army. (5) SIRA, the common equipment for combat simulation, must be extended to allow for the command and control of operations of air-mobile forces. (6) The basic training helicopter (SHS) is an indispensable equipment for the basic and advanced training of aircrews. The helicopter is not replaceable - especially with regard to affect training objectives.

A comprehensive evaluation of the ADS-33D handling qualities specification for military rotorcraft was completed with the BO 105 helicopter. The evaluation addressed both the quantitative and qualitative ADS-33 criteria. The evaluation of the quantitative or open-loop criteria in hover and in forward flight directly addressed applicability and repeatability of the criteria. The evaluation of the qualitative criteria or ADS-33 flight test maneuvers in the good visual environment addressed applicability and validity issues. This paper presents some of the major results of the quantitative and qualitative evaluations and extracts some lessons from the comparison of the results of both evaluations.

ONERA AND DLR COOPERATION ON THE SMART HELICOPTER CONCEPT: HANDLING QUALITIES DATA BASE FOR HOVER AND LOW SPEED FLIGHT

Bouwer, G., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Taghizad, A., Office National d'Etudes et de Recherches Aeronautiques, France; Moedden, H., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Apr. 1997; 8p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The handling qualities of a helicopter in the hover / low speed range were investigated with a lateral tracking task. The desired behaviour of decoupled rate command / attitude hold and attitude command systems were programmed in conceptual models with numerous sets of bandwidth / phase delay configurations. In a first step, the task was flown in a fixed base simulator. Then selected configurations were investigated in flight on a helicopter in-flight simulator. In the ground simulator, the pilots clearly preferred attitude command systems. In the flight tests, none of the attitude command systems was rated Level 1. For rate command / attitude hold systems, the configurations were rated with Level 1 and Level 2 with a clear boundary at a bandwidth of 2.5 rad/sec.

DEVELOPMENT OF A TACTICAL HELICOPTER INFRARED SIGNATURE SUPPRESSION (IRSS) SYSTEM

Sully, P. R., National Defence Headquarters, Canada; VanDam, D., Davis (W. R.) Engineering Ltd., Canada; Bird, J., Institute for Aerospace Research, Canada; Luisi, D., Department of National Defence, Canada; Apr. 1997; 12p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The world-wide availability of increasingly sophisticated but light weight infrared missile systems is presenting a serious threat to tactical helicopters in regional and peace-keeping operations. Part of the response to this threat lies in reducing as much as possible the infra-red signature of these helicopters. This paper briefly describes the nature of the threat presented by such missiles. The design and development of countermeasures in the form of IR suppression systems to reduce the engine exhaust produced signature is detailed. The results of experimental investigations and trials completed to date are described, along with the estimated potential for improving survivability. Future programmes and plans are summarized.

MODEL 412 COMPOSITE TAILBOOM

Mussett, G., Textron Bell Helicopter, Canada; Fewes, R., Textron Bell Helicopter, Canada; Apr. 1997; 10p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Bell Helicopter Textron is developing a technology demonstrator in the form of a Composite Tailboom for the Model 412 and 212 helicop-

ters, to potentially replace the existing metallic design. The composite tailboom has been designed for producibility and low cost whilst maintaining the capability to withstand the operating environment of the Model 412 and 212 helicopters. During the development of the tailboom, concurrent engineering philosophies were used so that manufacturing and tooling considerations were recognized in the design concept stage resulting in a very economical and producible design. Additionally the composite tailboom has been designed for fatigue with a high degree of redundancy in critical areas making it very tolerant to in service damage. This has been proven by an extensive material qualification and structural test program at Bell Helicopter. The composite tailboom is scheduled for flight test and FAA certification in 1996.

The paper describes the application of composite materials to the design of crash resistant beam and frame elements for helicopter subfloor structures, and discusses alternative fabrication technologies for these structural elements. These elements require a dual function structural concept with load carrying capability under flight loads and energy absorption under crash loads. The realization of this dual function by innovative design with fibre reinforced composite materials is described. In order to utilize these lightweight structural concepts in helicopters, cost effective technologies for series production of composite components are required. The paper discusses three fabrication methods based on autoclave technology, resin transfer moulding (RTM) and thermofforming, taking a sine-wave floor beam as a demonstrator component for the technologies.

INTRODUCTION OF BERYLLIUM ALUMINUM CASTINGS IN THE RAH-66 COMANCHE EOSS PROGRAM

Seinberg, J. P., Lockheed Martin Corp., USA; Tetz, D. P., Lockheed Martin Corp., USA; Raftery, K. R., Nuclear Metals, Inc., USA; Apr. 1997; 12p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Beryllium aluminum alloys, containing greater than 60 weight percent beryllium, are very attractive materials for lightweight and high-stiffness applications. However, due to the inherent problems associated with casting these alloys, processing of beryllium aluminum has generally been restricted to rolling and extrusion of pre-alloyed powder metal compacts. Nuclear Metals, Inc. (NMI), with technical and financial support from the Lockheed Martin Electronics and Missiles (LMEM) RAH-66 Comanche Electro-Optical Sensor System (EOSS) program, has recently developed a family of castable beryllium aluminum alloys suited for production using state-of-the-technology investment casting processes. These new alloys, identified as Beralcast(R), yield a fine grain homogenous microstructure with attractive mechanical, physical and thermal properties. The problems associated with producing beryllium aluminum castings, including molten metal reactivity and a wide solidification range, have been resolved by NMI and LMEM. As a result of the efforts to date, over fifty different Comanche EOSS components of various sizes and complexities will be produced using Beralcast(R) alloys. In certain cases, where designs are being modified to take full advantage of the Beralcast(R) properties, component weight savings of up to 50% over conventional materials can be achieved. Current focus is on the optimization of both casting and associated secondary support

processes, material characterization, non-destructive testing, and cost reduction. Developmental program goals, over the next eighteen months, being addressed in a series of programs funded by NMI, LMEM and the Army Aviation Research and Development Center, will provide the technology for the fabrication of large, complex precision investment castings. As a result of these efforts, Beralcast(R) investment castings will be available in time to support the RAH-66 Comanche EOSS demonstration/validation (Dem/Val) flight hardware program.

DUCTED TAIL ROTOR DESIGNS FOR ROTORCRAFT AND THEIR LOW NOISE FEATURES

Edwards, Bryan, Textron Bell Helicopter, USA; Andrews, Jim, Textron Bell Helicopter, USA; Rahnke, Chris, Textron Bell Helicopter, USA; Apr. 1997; 16p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

During the development of an advanced ducted tail rotor (DTR) design, a concentrated and successful effort was made to research and incorporate the low noise features of a DTR suitable for intermediate size rotorcraft. The design, whirl stand testing, and flight evaluations of this DTR configuration are described. Results of noise testing are presented for multiple design configurations to study the parametric effects of blade spacing, tip shape, rotational speed, and inflow turbulence. The acoustic effects of each parameter are presented, and measured noise reductions are identified. Isolated model ducted-rotor configurations are described, leading to additive noise level reductions of more than ten decibels for the DTR design. Installed on a Bell Model 222U helicopter, the DTR reduces total noise during hover and forward flight by an average of 2 to 6 dBA compared to the Model 222U configured with a standard tail rotor. A dramatic improvement in sound quality was found in subjective comparison tests. The performance and handling qualities of the test helicopter with the DTR prove to be similar to those characterizing a standard tail rotor. Component loads are well within design limits. These design qualities are discussed and substantiating test data are presented.

In order to characterize the potential sources of noise in a helicopter cabin and to validate a model of the cabin based on the SEA (Statistical Energy Analysis) method used as a predictive method, measurements were made by the ONERA Structures Department vibroacoustical team at EUROCOPTER FRANCE in Marignane while the SEA modeling was being carried out. Experimental equipment used in the single-engine helicopter ECUREUIL, data recording and analysis procedures are described and results are analyzed for different flight speeds. The SEA model of helicopter cabin is then presented and the way to take into account the different sources of excitation in this model. A model of aerodynamic excitation (due to turbulent boundary layer) is based on a simplified numerical approach. Finally, a comparison between measurements and computation for vibration response of structural parts and acoustical pressure in the cabin is presented.

UPGRADING OF CLASSICAL LIFTING-LINE THEORY TO OBTAIN ACCURATE FLIGHT MECHANICAL HELICOPTER MODELS: IMPROVED CORRECTION FOR SWEEP EFFECTS

vanHolten, T., Technische Hogeschool, Netherlands; Apr. 1997; 10p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In the usual analysis of the helicopter rotor, models and concepts are used which originate from classical lifting line theory. A theory, strictly valid for the analysis of straight high aspect ratio wings in steady flow. In the case of a helicopter rotor blade, the validity of these models is questionable since its sections encounter unsteady and yawed flow. Asymptotic theory shows how in this case more correct models may be synthesized. The present paper deals with an improved correction for the effect of sweep on the tilt of the rotor's tip path plane. Its application to a simple test case shows that the prediction of its lateral tilt is considerably affected. The new model for sweep effects might thus explain the often observed peak of the lateral tilt at small flight velocities.

AN EMPIRICAL CORRECTION METHOD FOR IMPROVING OFF-AXES RESPONSE PREDICTION IN COMPONENT TYPE FLIGHT MECHANICS HELICOPTER MODELS

Mansur, M. Hossein, Army Aviation Systems Command, USA; Tischler, Mark B., Army Aviation Systems Command, USA; Apr. 1997; 10p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Historically, component-type flight mechanics simulation models of helicopters have been unable to satisfactorily predict the roll response to pitch stick input and the pitch response to roll stick input off-axes responses. In the study presented here, simple first-order low-pass filtering of the elemental lift and drag forces was considered as a means of improving the correlation. The method was applied to a blade-element model of the AH-64 Apache, and responses of the modified model were compared with flight data in hover and forward flight. Results indicate that significant improvement in the off-axes responses can be achieved in hover. In forward flight, however, the best correlation in the longitudinal and lateral off-axes responses required different values of the filter time constant for each axis. A compromise value was selected and was shown to result in good overall improvement in the off-axes responses. The paper describes both the method and the model used for its implementation, and presents results obtained at hover and in forward flight.

EFFECT OF PROPULSION SYSTEM DYNAMICS ON ROTORCRAFT AEROMECHANICAL STABILITY IN STRAIGHT AND TURNING FLIGHT

Guglieri, Giorgio, Politecnico di Torino, Italy; Celi, Roberto, Maryland Univ., USA; Quagliotti, Fulvia, Politecnico di Torino, Italy; Apr. 1997; 8p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In recent years there has been growing interest in improving the fidelity of mathematical models of helicopter flight dynamics through a more accurate representation of the main rotor dynamics. The main objective of this paper is to study the effect of several parameters of the propulsion system on the aeromechanical characteristics of a hingeless rotor helicopter, both in straight flight and in coordinated turns. The effects of these parameters on the handling qualities of the aircraft will also be examined (pitch and roll frequency response).

AERODYNAMIC AND ACOUSTICS OF ROTORCRAFT: A SURVEY OF THE 75TH FLUID DYNAMICS PANEL SYMPOSIUM, BERLIN

Koerner, H., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Pahlke, K., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Apr. 1997; 18p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A survey of the 75th Fluid Dynamics Panel Symposium is given. The paper concentrates on dynamic stall, experimental investigations on helicopter rotors, 3D aerodynamic prediction methods and acoustic prediction methods. CFD methods were applied to dynamic stall on oscillating airfoils. The agreement with experimental data is acceptable for light and medium stall if appropriate turbulence models are used and the transition is fixed. None of the methods was able to accurately predict deep dynamic stall. A large effort was spent for the investigation of the Blade Vortex Interaction (BVI) noise. New national and multi-national experimental campaigns were conducted. Several researchers worked on the development and validation of aerodynamic and acoustic prediction methods for BVI. The efficiency of Higher Harmonic Control and of Individual Blade Control inputs for the reduction of BVI noise were investigated. The blade vortex miss distance was found to be the most important parameter for BVI noise. Methods for the prediction of high speed impulsive noise have been developed and encouraging results were presented.

THE INTEGRATED DEVELOPMENT OF A MEDIUM LIFT MILITARY/CIVIL HELICOPTER

Graham, J. P., Westland Helicopters Ltd., UK; Apr. 1997; 12p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The EH industries EH101 medium sized rotorcraft is the first of its kind to achieve production status that has been designed from the outset as a vehicle able to meet, without significant compromise, all appropriate civil and military regulatory requirements. Now that the design and development programme is nearing completion it is an appropriate time to review the success of the joint civil/military programme strategies which were implemented by EH Industries from the outset and which have significantly shaped both the product of the programme (EH101) and the programme design process.

This paper seeks to explore the application of thrust and lift compounding as a cost efficient development of the traditional helicopter. The principal deficiencies of the edgewise rotor are examined and the use of compounding to overcome these limitations and enhance rotorcraft capabilities, is developed. Potential missions suitable for the various types of compounding and the concept of a family of vehicles to cover a wide variety of applications are discussed. A possible technology demonstrator, based on a Lynx airframe and its build standard are described. Finally a list of overall conclusions are drawn.

RAH-66 COMANCHE PROGRAM STATUS

Linden, Arthur W., Sikorsky Aircraft, USA; Stieglitz, Martin H., Sikorsky Aircraft, USA; Apr. 1997; 10p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In an era of ever changing threats and declining defense budgets, the U.S. Army strategy is to procure systems that incorporate new technology and that leverage existing battlefield systems to fix war fighting deficiencies. The RAH-66 Comanche exemplifies this

strategy. Developed through an evolutionary series of analyses, simulations, tests and demonstrations, the Comanche weapon system integrates war fighting capability to provide battlefield overmatch, while minimizing the cost of ownership to the Army. Comanche is an integrated advanced weapons system designed to operate and survive on the combined arms digital battlefield. Its Low-Observable (LO) characteristics protect the element of surprise and reduce the detectability of the aircraft, thus increasing survivability. Comanche's advanced sensor suite provides the aircraft effective standoff while allowing it to remain undetected by the enemy and still operate within onboard armament system range. This capability allows the pilot to correctly identify targets and can effectively reduce fratricide under nonlinear operations. The Comanche's advanced digital communication system makes Comanche the targeting element for the Army's long-range advanced shooters like the Multiple Launch Rocket System (MLRS) and the Army Tactical Missile System (ATACMS). This paper provides an update to the development status of the RAH-66 Comanche helicopter. Section 2 reviews key technologies that form the heart of Comanche. Section 3 explains the Comanche design affords rapid deployability and low-cost supportability. The extensive use of simulation throughout Comanche development is described in Section 4. The success of the Comanche program rests in large part on the successful teamwork that is integral to all program activities. Section 5 explains the Team Comanche approach. Finally, Section 6 describes the plan to field the Army's 21st century reconnaissance attack helicopter in 2006.

The Bell-Boeing V-22 Osprey Tiltrotor is an unique aircraft capable of landing vertically like a helicopter, flying at speeds in excess of 300 KTAS like a turboprop, with the added feature of folding the rotor/wing for deployment from shipboard for US Navy/Marines operations. During the development of the V-22 and subsequent 1000+ hours of flight testing, many technical challenges were encountered and overcome. These challenges included aerodynamic characteristics of the wing, tail buffet, hover performance, hover downwash, structural loads limiting, vibration reduction, landing gear fatigue life, and control law design/Handling Qualities. This paper presents an overview of many of these challenges, discusses the techniques used to perform analysis and flight test, and presents results of the relevant portions of the test program.

In recent years, numerous studies have been centered on a novel class of materials which are capable of changing their shapes, imparting forces and generating moments as a function of applied electrical signals. This study is centered on one application of these 'adaptive' materials to achieve rotor flight control. A pair of twist-active directionally attached piezoelectric (DAP) torque-plates constructed from PZT-5H piezoceramic sheets laid up on an aluminum substrate were bonded rigidly to a rotor shaft.

Power margin is a standard measure of helicopter performance. However, in the competitive market place of today, performance is also an economic measure—cost to operate. Engine technology has significantly reduced fuel consumption and advances in composite technologies have produced lightweight structures. External weapons increase an armed helicopters parasite drag by 40% to 50%. Drag reduction is, therefore, the next largest contribution to fuel savings with figure-of-merit and rotor lift/effective drag ratio improvement the next two important areas. This paper explores the advances made in rotor blade design technologies following the UH-60 and Apache. The performance of an advanced airfoil rotor design is compared to the UH-60 and other existing helicopters to quantify the advancements. The methodology and analytical tools used to predict the performance of the advanced airfoil rotor is completely described. The resulting rotor system is then used to examine a number of options selected to reduce the drag contribution of external stores.

The mission performance of an armed helicopter does not only depend on its weapon system's efficiency. Other factors like the helicopter performance and in particular the handling qualities of the overall helicopter/weapon system may significantly affect mission performance. Since handling qualities cover a wide range of aspects which sometimes are difficult to quantify, it is useful to refer to existing standards when defining armed helicopters specifications.

Loads, dynamics/vibrations mechanics and acoustics are on one side classical disciplines which contribute to the integral helicopter layout. However in the context of weapon system integration they are the key areas where direct interfacing problems may arise between the basic helicopter and e.g. an external weapon store or a sight system.

The AH-64D Apache Longbow represents a significant enhancement in the evolution of attack helicopters. It is a fourth-generation precision weapon system that is totally integrated. The high level of integration provides an efficient and operationally effective system and gives commanders at all levels the ability to meet modern battlefield requirements ranging from peacekeeping to major regional conflict. This paper examines some of the AH-64D Apache Longbow capabilities, its inherent design features that maximize performance and provides a summary of the demonstrated level of performance.

The EH101 is a family of naval, utility and civil helicopters whose design and development have benefited from the different requirements of each of these operating regimes. The paper examines weapon integration on the EH101, focusing on the overall weapon system of which the helicopter is a major component. While the details provided are in most instances generic to all naval EH101 variants, specific details of the Royal Navy's Merlin Mk.1 helicopter are given where appropriate. The paper also outlines the highly complex contractual structures that lie behind the Merlin HM Mk.1 program. The paper concludes with a number of lessons that should be of advantage to future weapon integration programs.

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

After a brief recall of the principles of design load definition resulting from classical regulations, we show the difficulties of their application for combat aircraft equipped with Electrical Flight Control System (E.F.C.S.). This has led to an integrated process, where definition of design loads and setting of E.F.C.S. has been coupled, aiming finally to guarantee keeping the aircraft within a limit strength domain. This evolution reinforces the definition principle of limit loads as maximum loads to be expected in service, yet, without need for links with regulation standard maneuvers. We present the main aspects of this process, which includes: the definition of load severity indicators, and the elaboration of corresponding calculation operators; systematic calculations of these indicators during flight mechanics simulations (including real time development flight simulators); use of mathematical optimization techniques, allowing to handle exchange rate between maneuver performances and structural sizing. For general cases it is not proven that these evolutions could justify a modification of ultimate loads/limit loads safety factors.

Probabilistic composite design is described in terms of a computational simulation. This simulation tracks probabilistically the composite design evolution from constituent materials, fabrication process through composite mechanics, and structural component. Comparisons with experimental data are provided to illustrate selection of probabilistic design allowables, test methods/specimen guidelines, and identification of in situ versus pristine strength. For example, results show that: in situ fiber tensile strength is 90 percent of its pristine strength; flat-wise long-tapered specimens are most suitable for setting ply tensile strength allowables; a composite radome can be designed with a reliability of 0.999999; and laminate fatigue exhibits wide spread scatter at 90 percent cyclic-stress to static-strength ratios.

This paper describes a procedure for the evaluation of operational maneuver parameters and time histories, with the goal, to derive loads from operational flight parameters. The basic assumption is that for each operational maneuver type performed, in service or simulation as a set of normalized parameter time histories can be verified, and are called Standard Maneuvers. The Standard Maneuver is obtained by normalization of amplitudes and maneuver time to make the parameters independent of intensity of the maneuver, flight condition, flight control system, mass configurations, and the aircraft type. This paper outlines the determination of the operational maneuver parameters, the identification process of the maneuver types, the normalization procedure, the determination and verification of the Standard Maneuver time histories.

This paper describes the feasibility for the determination of operational loads applying an operational Maneuver Model. The essential input for the Maneuver Model is a set of Standard Maneuvers consisting of normalized operational parameter time histories. Operational external loads can be determined for: extreme operational loads, fatigue loads, and loads related to the operational parameters by introducing aircraft basic data, flight condition and boundary conditions for the maneuver to be considered. The application of the Maneuver Model is demonstrated for one aircraft. For some operational maneuvers the extreme operational loads are determined and compared with the design loads required by MIL-8861. The application of Standard Maneuver independent of the aircraft type has been demonstrated by determination of the loads applying the Standard Maneuver time histories from F-16 reconstituted to real time using the CF-18 performance data. The calculation of the loads has been performed using a proven Canadian loads calculation methodology and compared against flight test data of CF-18.

THE IMPACT OF DYNAMIC LOADS ON THE DESIGN OF MILITARY AIRCRAFT

Luber, W., Daimler-Benz Aerospace A.G., Germany; Becker, J., Daimler-Benz Aerospace A.G., Germany; Sensburg, O., Daimler-Benz Aerospace A.G., Germany; Feb. 1997; 28p; In English; See also 19970029334; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The layout of military aircraft structures is strongly influenced by dynamic loads from the early development phase onwards up to final design and clearance phase. Different dynamic loads have to be considered, namely dynamic gust loads, buffet loads on wing, fin, fuselage and also buffet loads from airbrakes, cavities and blisters, gunfire loads mainly at attachment frames and panels, Hammershock loads for air intake, bird strike and ammunition impact, acoustic loads for outer air intake and missile bays. Also dynamic loads from landing, jettison, brake chute and rough runway induced loads as well as wake induced loads may be designed. Dynamic loads resulting from flight test excitation like bunker input, stick jerks and control surface sweeps also have to be considered. For some of the designing dynamic loads, examples are given to explain their derivation and significance both for design of aircraft structural parts and related clearance aspects. Methods to derive dynamic design loads for different applications by using analytical and experimental tools will be presented. Validation methods for various design loads using dynamic model test results, wind tunnel model and flight test results are mentioned. The main purpose of this presentation is to indicate where dynamic loads would be dimensioning structures of future high performance combat airplanes and how to approach the problem of integrating all aspects into an optimum design.

DYNAMIC LOADING CONSIDERATIONS IN DESIGN OF MODERN COMBAT AIRCRAFT

Chapman, R., British Aerospace Defence Ltd., UK; Feb. 1997; 16p; In English; See also 19970029334; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The design and clearance for flight of recent aircraft has provided new challenges in the field of loads prediction and validation. Traditionally during the initial design phases of an aircraft project, dynamic loading effects have been covered by uncertainty tolerances applied to static loads. Only when structural or equipment qualification problems emerge during development testing, or worse in-service, have dynamic loading problems been fully addressed. The approach at BAe is to include dynamic loading at the design and development stage to a much greater extent than formerly. This is with the intention of reducing or eliminating the need for costly post-design investigations and/or structural redesign. This paper outlines the effects considered and some examples of the challenges encountered with respect to

project constraints/criteria, methods maturity and flight clearance procedures. As validation of dynamic loading predictions is essential to aircraft qualification and certification, examples comparing predicted and flight measured data are presented.

THE GROUND LOADS DURING PHASES OF ROLLING: THE CIVILIAN AND MILITARY SPECIFICATIONS LES CHARGES AU SOL LORS DES PHASES DE ROULAGE: LES SPECIFICATIONS CIVILES ET MILITAIRES

Sqeglia, G., Aerospatiale, France; Regis, O., Aerospatiale, France; Feb. 1997; 13p; In French; See also 19970029334; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche .

This article presents a comparative study of American, English, and French standards and civil specifications (JAR/FAR) applied to conditions of ground roll. The results obtained with small bumps, the actual surfaces, and the work accomplished within the framework of civil regulations are presented. The influence of these different regulations is explained in taking for example a civilian turboprop certified for operations on semi-prepared surfaces.

This article presents a review of the historical background of the growth of external loads and design requirements for the F-16 fighter aircraft. Several scenarios are recounted where analysis assumptions were determined to be inadequate and flight test or operational data presented situations not fully covered by design criteria. Changes in design requirements are discussed and suggestions for future aircraft design analyses are offered.

INFLUENCE OF THRUST VECTORING SYSTEM (TVS) ON STRUCTURAL DESIGN LOADS

Fuelhas, Konrad, Daimler-Benz Aerospace A.G., Germany; Neubauer, Martin, Daimler-Benz Aerospace A.G., Germany; Feb. 1997; 12p; In English; See also 19970029334; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The maneuverability and performance of modern fighter aircraft can be enhanced by a Thrust Vectoring System (TVS). This paper will show the benefits for the aircraft (e.g. Poststall) and identify the change in the structural design loads when a TVS will be adapted to an existing fighter aircraft. The requirement is to minimize structural changes under consideration of the benefits from the TVS for aircraft and performance. The capabilities and properties of new fighter aircraft to be designed initially including TVS will be touched on.

EUROFIGHTER 2000 STRUCTURAL DESIGN CRITERIA AND DESIGN LOADING ASSUMPTIONS

Watson, G. J., British Aerospace Defence Ltd., UK; Feb. 1997; 10p; In English; See also 19970029334; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

This paper provides an overview of the assumptions employed in the preparation of Design Loads for the Eurofighter 2000 aircraft. For loading purposes, a set of Design Criteria have been defined, which summarize the principal maneuver requirements for the aircraft. Addi-

tional assumptions on aircraft Control usage have been necessary to allow Design Loads to be defined without a detailed knowledge of the final standard of Flight Control System. The assumptions employed have been aimed at providing a robust structural design for the airframe, an aim which is now being validated through the Flight Clearance and Test activities on which the first Prototype aircraft are currently engaged.

COTS JOINS THE MILITARY

Anderson, L., Lockheed Martin Tactical Defense Systems, USA; Stevens, R., Lockheed Martin Tactical Defense Systems, USA; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The complexity of today's military system has caused the priority of affordability to rise to an unprecedented level among system requirements. An increasing number of government and defense industry leaders are relying on commercial off-the-shelf (COTS) products with the associated economies of scale and use of non-developmental items (NDI) to meet this requirement. The affordability benefits of COTS and NDI for military systems are subject to several other factors. For example, as the need for products capable of operating in a hostile military environment increases, the number of products and vendors meeting these requirements decreases. In addition, military systems, which traditionally have been expected to survive for long periods of time, are subjected to two commercial phenomena that occur simultaneously - product prices decrease over time while technology provides an increase in product performance. The latter factor results in a dichotomy summarized as parts obsolescence. This paper identifies additional military system issues and current commercial trends and postulates how these trends can be used to meet affordability requirements. The latter includes illustrated use of open system standards combined with pre-planned product improvement (P3I).

This Lecture Series covers systems update and structural airworthiness aspects of aging, fixed-wing aircraft. It highlights the aspect of retrofit/rejuvenation of aging aircraft through presentations relating to three front-line combat aircraft in NATO's inventory. The presentations describe the implementation strategies and ways to improve the ability of an airframe to accommodate new systems to meet present day mission requirements. Technical issues pertaining to structural safety, maintenance management, and proactive rehabilitation/retrofit schemes are also discussed. It provides technical information to fleet operators and managers to assist them to better manage aging aircraft fleets and be able to deal with aging related problems as they arise. It also targets industry personnel responsible for upgrading the capabilities of combat aircraft, maintenance personnel at air logistics centers, and specialists involved with the design of repairs and prescription of inspection methods. "Aging aircraft" has several connotations, amongst them technological obsolescence, performance upgrading, changing mission requirements unanticipated

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

during design specification and development, the specter of runaway maintenance costs, decreased safety, impairment of fleet readiness, and unavailability of home depot facilities.

The USA Air Force (USAF) has numerous aircraft that have already met or exceeded their original design service lives; many of these aircraft will considerably exceed their original life goals before they are retired from the inventory. Technologies are needed which will extend the lives and/or reduce the costs of these aging aircraft. Such technologies will insure flight safety, reduce maintenance and repair requirements and their associated costs, and increase operational readiness. A description of the USAF aging aircraft systems research and development efforts that are being conducted in the technology categories of Structural Integrity, Nondestructive Evaluation/Inspection, Avionics, Propulsion and Subsystems is presented. The structural integrity area considers damage that can degrade the service lives of aging aircraft; the technologies required to ensure aircraft structural integrity with such damage present are identified. Typical types of damage considered include corrosion, fatigue cracking, and the potential interaction of corrosion and fatigue. Also, the possible occurrence of widespread fatigue damage (WFD), which becomes more likely as aircraft structure ages, is addressed. Life extension methodology is described that includes the development of analytical and experimental procedures for the repair (e.g., composite patches) of metallic structure that will restore or extend the full service life the damaged structure.

AGEING AIRCRAFT: MANAGING THE TORNADO FLEET

Marlow-Spalding, M. J., Royal Air Force, UK; Oct. 1996; 16p; In English; See also 19970041535; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

During the 1980's the RAF procured a fleet of 228 Strike/Attack and 170 Air Defense Tornado aircraft to form the back-bone of its long term fleet of combat aircraft. The Tornado aircraft was designed using 1970's technology, with a planned in-service life of 4000 flying hours and 100 Fatigue Index. The aircrafts original out of service date was 2003. Since then the primary use of the aircraft has changed to one of providing out of area support to United Nations and NATO operations. Furthermore, the aircraft's life has been extended so that it is now anticipated that the RAF will continue to fly the ADV until about 2010 and the IDS to approximately 2018, by which time the individual in-service aircraft will have accrued some 9000+ flying hours. To meet the challenge the RAF has had to address how the airworthiness of the airframe and flight safety critical components can be assured, whilst at the same time, ensuring that the aircraft continue to provide an operationally effective weapon platform at a time of unprecedented, technological advances.

CANADIAN CF-18 STRUCTURAL LIFE MANAGEMENT PROGRAM

Simpson, D. L., National Research Council of Canada, Canada; Oct. 1996; 36p; In English; See also 19970041535; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The Canadian Forces purchased 135 CF-18 A/B Hornet aircraft in the 1980's. Usage of the CF-18 in the Canadian role was and continues to be substantially different than that defined in the original design requirements. The early usage of the aircraft was very harsh in comparison to design and there were strong indications that airframes would have to be retired before reaching their design service life of 6000 hours. This situation required the adoption of a vigorous and proactive program to manage the structural life of the aircraft. This lecture describes the situation in some detail and then provides descriptions of the programs initiated to gain control over the operational usage and to develop the engineering data that will allow cost effective and safe operation of the aircraft to at least 6000 hours.

Several systems upgrades have occurred throughout the life of the F-16 aircraft. This paper briefly discusses various system upgrades including navigational equipment, communication equipment, radar, stability and control, flight control system, and engines. The F-16 was originally designed to be a lightweight fighter with a service life of 8,000 flight hours. Due to the usage being more severe than design and an increase in weight, several structural modifications were necessary to keep the F-16C/D in service. The structural modification program known as "Falcon Up" is being accomplished by several countries for the F-16A/B/C/D aircraft. The program began in June 1993 for USAF and will complete around the year 2001. This paper discusses each of the structural problems and the modifications necessary to reach an 8,000 hour service life.

CORAL REACH: USAF KC-135 AGING AIRCRAFT PROGRAM

Davidson, Paul E., Oklahoma City Air Logistics Center, USA; Oct. 1996; 8p; In English; See also 19970041535; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper is intended to serve as an aid to any aircraft manager beginning to develop or expand an aging aircraft program. It is based on the experiences of the USAF KC-135 aircraft program since the early 1990's as they have fought to gain recognition and support for the issues faced by that program. CORAL REACH is a USAF program responsible for developing a GRAND STRATEGY for all age related issues on the C/KC-135 aircraft fleet. It is intended to ensure a logical, comprehensive and proactive program to sustain the aircraft until retirement. Today, the KC-135 aircraft have an average age of 38 years and many are expected to serve until the year 2040. Specific life extension efforts for the aircraft are dependent on the outcome of analyses and studies performed by the Integrated Product Team (IPT) incorporated under the CORAL REACH program. These analyses and studies focus on the technical, economic and safety aspect of the issues and become the basis for future actions to deal with the effects of an aging aircraft fleet.

This paper discusses structural life enhancement through prestressing techniques such as cold working, shot peening, laser shock processing, etc. The state-of-practice methods of repairing metallic and composite structures are outlined. Advanced repair methods such as composite patch repair of cracked metallic struc-

tures are shown. Finally, improved properties of advanced metallic materials are shown and their in-service applications to spare parts is discussed.

The life of a weapon system is influenced to a high degree by the structural integrity of the airframe. Numerous programs to insure this have been established within NATO's Air Forces. Structural loads, leading to fatigue as well as corrosion, depending on the usage environment, are the major reason for the degradation of structures. The many different classes of loads, the generation of loading conditions during the design phase, consideration of static and fatigue loads for structural lay-out and their validation are presented. The fatigue life of aircrafts in service is different from the design life for many aircrafts not only due to the extended need for the airframe as a platform for new/upgraded systems (life extension), but also due to different usage compared to the design spectrum. Monitoring of the life consumption is therefore essential. Methods and concepts to establish the "used life" are described for two different aircrafts and the influence of A/C-roles and -equipment as well as structural weight increase over time are discussed.

CORROSION PREVENTION SYSTEM FOR THE F-16 FIGHTER AIRCRAFT

LaCivita, Kenneth J., Aeronautical Systems Div., USA; Oct. 1996; 28p; In English; See also 19970041535; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The Corrosion Prevention System for the F-16 Fighter Aircraft is an excellent example of defining the design, materials, and process selection requirements early in the acquisition program. This process necessitates working closely with the contractors and customers throughout the life of this program and establishing and maintaining a Corrosion Prevention Advisory Board (CPAB). The corrosion prevention system used on the F-16 implements materials, surface treatments, finishes, and coating systems, that provide superior corrosion protection when manufactured and maintained properly. The F-16 has nevertheless suffered from some corrosion related problems. Although many of these problems have been corrected, field corrosion surveys are useful in identifying new issues as well as past problems that have not been adequately addressed. Results of recent field study conducted by the F-16 System Program Office (SPO), miscellaneous items from the CPAB meetings, and continuing changes brought about by environmental, health, and safety compliance provide the need for a strong, dynamic, on-going corrosion prevention program.

Recent trends in research activities are primarily geared to design future air vehicles smart so as to perform roles beyond those performed by conventional vehicles including: (1) Improved performance; (2) Reduced structural weight; (3) Reduced pilot load; (4) Increased survivability and reliability; and (5) Reduced maintenance requirements. From the structural engineer's point of view the key

areas of interest are: (1) Avionics/structures integration to reduce structural weight; (2) Smart structures to improve performance, reduce maintenance cost and improve safety of flight; (3) Smart skins to reduce structural weight and improve antenna performance; (4) Infra-red (IR) signature reduction to improve survivability; and (5) Thermal management to improve performance. The majority of the research in these areas is applicable to future aircraft, however, smart structures technology has applications to in-service aging aircraft to assure the safety of flight and reduce maintenance cost.

DURABILITY AND DAMAGE TOLERANCE

Rudd, James L., Wright Lab., USA; Oct. 1996; 24p; In English; See also 19970041535; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Durability and damage tolerance are two of the most critical elements of a structural integrity program for aging aircraft. Durability is primarily concerned with economic issues, dealing with maintenance and repair requirements and their associated costs. Damage tolerance is primarily concerned with structural safety, precluding the occurrence of catastrophic failure. Both durability and damage tolerance can affect the operational readiness of aging aircraft. Significant issues involving durability and damage tolerance are widespread fatigue damage (WFD) and structural repairs. This paper considers three topics of widespread fatigue damage.

UNMANNED TACTICAL AIRCRAFT: A RADICALLY NEW TACTICAL AIR VEHICLE AND MISSION CONCEPT

Gardner, Pat, Science Applications International Corp., USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 12p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Unmanned Tactical Aircraft (UTA) is a complete air-power system which enables a general purpose high performance aircraft to perform a full range of lethal missions without the physical presence of a pilot in the aircraft. The system allows the pilot to be virtually present, so that his moral and tactical judgment are retained without exposing him to capture or casualty. Without the pilot, the air vehicle will be optimized for a combination of performance and affordability and can be much less complex and expensive than a comparable manned vehicle. UTAs will be effective in a variety of missions in conflict situations but need not be flown in peacetime beyond minimum maintenance needs; training and mission rehearsal will be done using simulations with the actual virtual pilot interface in the loop. This concept will enable unprecedented affordability in the system. Current estimates are up to 40% reduction in acquisition cost and 50% reduction in operations and support cost. A mix of manned aircraft and UTAs, both exploiting the emerging information architecture for targeting and control provides a distinct new option for national air forces which may be unable to afford a "full" force structure of manned aircraft in the constrained budget environments of the future.

VEHICLE CONFIGURATIONS AND AEROTHERMODYNAMIC CHALLENGES CONFIGURATIONS DE VEHICULES ET DEFIS DE LA CONCEPTION AEROTHERMODYNAMIQUE

Perrier, P. C., Dassault Aviation, France; Hirschel, E. H., Daimler-Benz Aerospace A.G., Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 16p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Sustained hypersonic flight appears as a challenge for 3 classes of concepts quite different in their use: one is relative to constant cruise, the second to transient (but slowly varying) high altitude flight,

the latter to low altitude penetration. For each of the concepts, a review will be presented of the more promising configurations and the associated aerothermodynamic challenges. In conclusion a proposal for a common technology program is given with demonstration filling the envelope of specifications and dealing with the critical points they generate. Slowly varying high altitude flights may be part of the mission of satellite launchers in the acceleration phase or in reentry cross range cruise with or without rebounding effects. During these flights, convective ratio to radiative heat transfer is a driving parameter of vehicle configuration, associated with the search for better lift over drag ratio. Low altitude penetrators are specified by the high pressure generated and heavy flutter requirements. On the contrary, the search for configurations with relatively low drag and fuel consumption per mile, for a minimum structural weight, leads to configurations of pure cruisers to be at the pinpoint of aerodynamic efficiency only compromised by carry-and-release constraints.

HEAT LOADS IN HYPERSONIC VEHICLE DESIGN

Hirschel, E. H., Daimler-Benz Aerospace A.G., Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 10p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Heat load of hypersonic vehicles flying in the earth atmosphere at speeds below 8 km/s are considered. The general aspects are discussed, definitions are given. Surface-radiation cooling as the basic cooling mode is investigated, related peculiarities are explained. It is shown that heat loads are not only of interest for the materials and structure layout, but that strong couplings in both directions exist with the aerodynamic shape and the aerodynamic performance. The heatloads oriented design as a perspective is discussed. Finally an overview over the status and the development needs of the prediction and verification capabilities is given.

In this paper, we discuss some of the more difficult to predict phenomena that control the sizing of thermal protection systems for sustained hypersonic flight, and the methods which are available to provide estimates of the requirements for backface, film-cooling and transpiration cooling techniques. The prediction of boundary layer transition on leading edges, in regions of pressure gradient, shock interaction and crossflow induced by vehicle incidence, represents key tasks in vehicle design. We review prediction methods that can be used to estimate the thermal loads when transition occurs. Film and transpiration cooling are two techniques that can be employed to flexibly handle the large and spatially-variable heating loads that can occur in shock interaction regions in and around airbreathing propulsion systems for hypersonic vehicles. Correlation of measurements made to assess the performance of these systems are presented to provide estimates of their effectiveness in constant pressure and shock interaction regions.

DESIGN OF HIGH L/D VEHICLES BASED ON HYPERSONIC WAVERIDERS

Eggers, Th., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Strohmeier, D., Deutsche Forschungsanstalt fuer Luft- und

Raumfahrt, Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 10p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The aerodynamic behavior of a waverider representing the hypersonic lower stage of a TSTO system is discussed. The investigation covers the complete speed range from subsonic high lift up to hypersonic flight close to the design point of the waverider geometries. Several interesting flow phenomena are described which govern the aerodynamic behavior. It is found that the favourable off-design behavior of hypersonic waveriders allows the practical use of waverider vehicles far away from their particular design flow conditions. Studies concerning the planform show, that the modification of a gothic planform towards combined forebody - delta wing planforms allows a significant improvement of the aerodynamic efficiency L/D in sub- and transonic flow. In addition the longitudinal stability is increased without compromising the favourable high speed qualities. These benefits are partly compensated by an increasing neutral point shift along the trajectory.

FLIGHT TESTING FOR HYPERSONIC SPEEDS: AN EUROPEAN VIEW

Laruelle, Gerard, Aerospatiale, France; Bonnefond, Thierry, Aerospatiale, France; Sacher, Peter, Daimler-Benz Aerospace A.G., Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 6p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The development of future vehicles with sustained hypersonic flight, using air-breathing and/or rocket propulsion, will require new knowledge and technologies which are not yet available and therefore not validated. One of the mandatory next steps before entering prototype work will be to perform flight tests in order to investigate the topics which can not be studied on ground. The present scenario in US (HyTech, X 33, X 34,...), Japan (Orex, Hyflex, Alflex,...) and Europe including Russia shows worldwide effort in exploring the need for flight testing advanced technologies flying at hypersonic speed. This need will be even more evident for future space launchers if reusability is required. In that case, this will mandatorily lead to a step-by-step approach by flight testing technologies using appropriate flying test beds. Airbreathing propulsion is still, of course, most challenging due to the problems of engine/airframe integration and to the lack of flight data during engine operations at hypersonic speed. Even for fully reusable rocket propulsion, a lot of uncertainties must be still necessarily decreased before starting development of a future advanced transportation system.

NASA HYPERSONIC X-PLANE FLIGHT DEVELOPMENT OF TECHNOLOGIES AND CAPABILITIES FOR THE 21ST CENTURY ACCESS TO SPACE

Hicks, John W., NASA Dryden Flight Research Center, USA; Trip-pensee, Gary, NASA Dryden Flight Research Center, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 10p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

A new family of NASA experimental aircraft (X-planes) is being developed to uniquely, yet synergistically tackle a wide class of technologies to advance low-cost, efficient access to space for a range of payload classes. This family includes two non-air-breathing rocket-powered concepts, the X-33 and the X-34 aircraft, and two air-breathing vehicle concepts, the scramjet-powered Hyper-X and the rocket-based combined cycle flight vehicle. This report describes the NASA vision for reliable, reusable, fly-to-orbit spacecraft in relation to the current space shuttle capability. These hypersonic X-plane programs, their objectives, and their status are discussed. The respective technology sets and flight program approaches are compared and contrasted. Additionally, the synergy between these programs to

advance the entire technology front in a uniform way is discussed. NASA's view of the value of in-flight hypersonic experimentation and technology development to act as the ultimate crucible for proving and accelerating technology readiness is provided. Finally, an opinion on end technology products and space access capabilities for the 21st century is offered.

High speed air-breathing vehicle studies (missiles, combines cycle engines single or two stage-to-orbit launchers) have been undertaken at AEROSPATIALE and ONERA for many years. The design of these vehicles requires the study of air intakes. The choice of the air intakes to be installed on a given vehicle is related to different considerations, among which the type of vehicle, its mission and expected performances, other constraints such as propulsive system integration, stealthiness,.... The study of inlets can not be uncoupled from the design of other vehicle elements. Indeed, for hypersonic vehicles, the forebody usually acts as a pre-compression ramp and the scramjet injection struts take part of the internal compression process: both of these elements have to be taken into account at the very beginning of the inlet design, as well as flowfield requirements for combustion. For the supersonic vehicles using ramjets, though the forebody flowfield has less importance on the inlet design than for the hypersonic case, strong interactions exist between the inlet and the combustion chamber; and this, not only in terms of system performances, but also in terms of acceptable flowfield distortions for the combustion.

SYSTEMS CHALLENGES FOR HYPERSONIC VEHICLES

Hunt, James L., NASA Langley Research Center, USA; Laruelle, Gerard, Societe Nationale Industrielle Aerospatiale, France; Wagner, Alain, Societe Nationale Industrielle Aerospatiale, France; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 18p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper examines the system challenges posed by fully reusable hypersonic cruise airplanes and access to space vehicles. Hydrocarbon and hydrogen fueled airplanes are considered with cruise speeds of Mach 5 and 10, respectively. The access to space matrix is examined. Airbreathing and rocket powered, single- and two-stage

vehicles are considered. Reference vehicle architectures are presented. Major systems/subsystems challenges are described. Advanced, enhancing systems concepts as well as common system technologies are discussed.

SCIENTIFIC BARRIERS TO HYPERSONIC VEHICLE DESIGN

Sakell, Leonidas, Air Force Office of Scientific Research, Bolling AFB, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 6p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper will discuss some of the scientific barriers to operational hypersonic vehicle design. These barriers arise from three primary sources. The first is a lack of fundamental understanding and knowledge of the aerothermodynamic flows, environments and, flow processes which arise over complex, 3D weapon system flight configurations during flight. The second source is the limitations inherent in the numerical simulations of these flows. The third is the lack of hypersonic test facilities which can operate with test times of at least seconds while also duplicating flight enthalpies and Reynolds numbers. My interest centers about the scientific issues arising with actual hypersonic configurations that are of current, planned or, potential mission relevance to the USA Air Force. I will discuss the major barriers in these categories below from the perspective of their impact on hypersonic flight vehicle design and performance.

MULTIDISCIPLINARY OPTIMIZATION METHODS FOR PRELIMINARY DESIGN

Korte, J. J., NASA Langley Research Center, USA; Weston, R. P., NASA Langley Research Center, USA; Zang, T. A., NASA Langley Research Center, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 10p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

An overview of multidisciplinary optimization (MDO) methodology and two applications of this methodology to the preliminary design phase are presented. These applications are being undertaken to improve, develop, validate and demonstrate MDO methods. Each is presented to illustrate different aspects of this methodology. The first application is an MDO preliminary design problem for defining the geometry and structure of an aerospike nozzle of a linear aerospike rocket engine. The second application demonstrates the use of the Framework for Interdisciplinary Design Optimization (FIDO), which is a computational environment system, by solving a preliminary design problem for a High-Speed Civil Transport (HSCT). The two sample problems illustrate the advantages to performing preliminary design with an MDO process.

Design for Affordability is the new paradigm for the 21st Century. Balancing the conflicting goals of systems superiority and systems affordability is the challenge of the integrated design environment on a larger scale than has ever been done before. This paper discusses the engineering processes and tools of Integrated Design which contribute to affordability of combat aircraft structures. The objectives

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

of integrated design are to ensure a balanced design so that no single performance parameter dominates the system and to manage the design achieves the optimum in system level performance and affordability. Analyses and simulations reduce the risk in the preliminary design phase, minimizing the amount of testing required for validation prior to production.

Combat aircraft design is a complex task requiring a balance to be struck between potentially conflicting requirements. Most recently the very practical consideration of affordability has come to dominate almost every phase of the process. However, the requirement for effectiveness remains. This paper considers how the application of large scale simulation and modelling - dubbed 'Synthetic Environments' can already assist in understanding the issues and trade-offs and goes on to suggest how the potential of the approach may in due course extend to a far wider range of applications. The paper draws on examples of research into Synthetic Environments as an approach and will address some of the work on SEs and their applications in which the UK Defence Evaluation and Research Agency is involved. AGILITY IN THE CONTEXT OF IMPROVED OPERATIONAL EFFECTIVENESS

McKay, K., British Aerospace Defence Ltd., UK; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 10p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The environment in which a fighter pilot operates is subject to continual change due to technology advances and the altering world situation. The only prediction which can be made with confidence is that profound change should continue to be expected. The first air to air conflicts occurred in the Great War. Here, aircraft were, for the most part marginal with regard to performance, stability and controllability. Indeed, many combat losses could be attributed to these shortcomings rather than the action of the enemy. However, some of the aircraft were regarded, and still are, as models of the agile fighter, particularly in the hands of an expert pilot, or "ace". The basic skills required were the ability to remain in control and shoot accurately. For subsequent conflicts, the same basic skills were required, although airframes were better stabilised and controlled and had increased power available, resulting in higher speeds. With radar and radio, it became possible to receive guidance towards the targets that the ground control perceived as the prime threat. Weapons remained visual range, however, but regardless of this, the increased speeds and the added information changed the difficulty of the pilot's task due to the implications on his situational awareness and choice of tactics. Increasingly, the combat results became more clouded by the interaction of the systems available to the pilot and his ability to assimilate the information provided. Author

THE BENEFITS OF THE PASSIVE AND ACTIVE AEROELASTIC DESIGN OF AIRCRAFT STRUCTURES

Hoenlinger, H. G., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Hutin, P. M., Office National d'Etudes et de Recherches Aerospatiales, France; Pendleton, E. W., Wright Lab., U-

SA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 24p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The increasing performance requirements and the economical pressure to reduce Direct Operational Costs (DOC's) of new aircraft design can no longer be met by traditional and sequential design processes. This is especially true when considering aeroelasticity. The impact of aeroelastic effects on the design of new high performance transport or fighter aircraft demands the use of multidisciplinary design concepts and optimization strategies in the preliminary design phase or earlier to develop flutter-free structures and to ensure excellent multipoint design characteristics. This paper presents selected examples of a variety of aeroelastic design principles for passive primary aircraft structures and for active structures of advanced aircraft with highly sophisticated fly-by-wire flight control systems.

V/STOL AND STOVL DESIGN CONSIDERATIONS

McErlan, Donald P., Naval Air Systems Command, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 4p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A01, Hardcopy; A03, Microfiche

As has been noted in many studies of this class of aircraft (cf "Aircraft Design Integration" L.M.D.C. Campos, Aerospace 2020) full vertical take off and landing of attack type aircraft (non-rotor powered) has been shown to be an unwise design option. This is due primarily to the substantial amount of thrust which must be provided for vertical lift severely limiting gross weight and therefore either payload or range. However, if even a limited amount of forward motion is provided, so that a conventional lifting wing augments the vertical thrust of the propulsion system the situation changes considerably. This combination of wing and propulsion produced lift has been shown to provide both useful payload/range combinations and significantly shortened take-off roll. Upon completion of the mission, with either payload expended or fuel load consumed, the system is now sufficiently lighter so that vertical landing does become possible. This gives rise to a class of aircraft known as "STOVL" or Short Take Off/Vertical Landing. Obviously one could also design the aircraft with shortened landing distances but not truly vertical. However, an interesting systems trade comes to bear on the problem.

A DISCUSSION OF A MODULAR UNMANNED DEMONSTRATION AIR VEHICLE

Cherry, Mark C., Wright Lab., USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 9p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The idea of an unmanned combat vehicle has existed for many years. We now have the opportunity to capitalize on numerous technologies under development to make an unmanned combat vehicle a viable option for military commanders. The key problems are the issues dealing with the integration of these technologies into a synergistic aeroform, and the human control problems that arise due to these technologies. A modular demonstration platform that can capitalize on new technologies as they mature is a key way to demonstrate the viability of an unmanned combat vehicle, as well as answer some of the questions, and technology challenges, that may arise due to off-board control of a lethal air vehicle. A modular airframe is required in a demonstration platform to flight test and demonstrate various technology sets as they mature. Modularity is important because it provides greater system flexibility and should reduce the life cycle costs of the air vehicles. The demonstration platform must be capable of performing a notional mission similar to what may be envi-

sioned for a combat UAV, in order to show that demonstrated technologies are applicable to production vehicles. The challenges and payoffs of this aggressive vision will be discussed.

K., Institute for Aerospace Research, Canada; Immarigeon, J-P., Institute for Aerospace Research, Canada; Wallace, W., Institute for Aerospace Research, Canada; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 16p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The presence of aging aircraft fleets has been increasing throughout the world due to the global, financial, and political environment. The reduction in the defense budget of many countries has forced them to use their military aircraft well beyond their original design lives. Also, the demand on the performance of these aircraft has been increasing due to increased payload and severe usage. Maintaining the airworthiness of these aircraft and their propulsion systems while at the same time keeping the maintenance costs low is of prime concern to the operators and regulatory authorities. The flight safety requirements and the performance demands are likely to result in higher maintenance costs. However, the unique opportunities provided by the research and development in the areas of new and improved materials, structures, manufacturing, repairs, and Non-Destructive Inspection (NDI) technologies have made it possible to keep the increase in costs to a minimum and in many cases reduced the overall maintenance costs. This paper discusses the contributions made by research and technology towards lowering the maintenance cost and improving the flight safety of aging airframes and engines.

SMART AIRCRAFT STRUCTURES

Crowe, C. Robert, Defense Advanced Research Projects Agency, USA; Sater, Janet M., Institute for Defense Analyses, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 16p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The broad but strongly interdisciplinary field of smart structures and materials seeks to apply multi-functional capabilities to existing and new structures. By definition, smart structures and materials are those which can sense external stimuli and respond with active control to that stimuli in real or near-real time. The most common analogy is to a human (Figure 1): the nervous system senses the stimuli; then the brain processes the information causing a muscle (actuator) to respond. For purposes of this paper, smart structures and materials consist of active devices—primarily sensors and actuators either embedded in or attached to a structure. Smart structures analogy to a human. These smart structures technologies are expected to provide new and innovative capabilities in future military aircraft including fighter and transport aircraft, unmanned aerial vehicles (UAVs), and helicopters and tilt rotorcraft. Specific applications are described in terms of system functional capability enhancements (e.g., vibration damping and suppression) and overall system performance benefits (e.g., reduced life cycle costs).

SERVICE RELEASE AND 'SAFETY CRITICAL' SOFTWARE

Rodger, K. S., Defence Test and Evaluation Organisation, UK; Advances in Flight Testing; Dec. 1997; 10p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

As is well known, software is increasingly used to improve operational effectiveness. It is also well known that every innovative use of

technology results in a change to the types of hazard and therefore introduces the potential for reduced safety. This paper considers what is required to recommend release of aircraft into service when safety is dependent on the "correct" operation of software. The paper starts with a general description of a release to service and of how it should be derived and continues with a discussion of testing its and roles, contributions and its limitations. Since software is inevitably associated with electronics the paper next considers how the safety implications of using electronics should be assessed before consideration of how safety critical software should be treated by certifying authorities. The views expressed in this paper are those of the author and are not necessarily DTEO policy.

C-17 ENHANCEMENTS TO A FLIGHT TEST PLANNING PROGRAM

Canody, Cheryl, Tybryn Corp., USA; Hewett, Marle D., G and C Systems, Inc., USA; Advances in Flight Testing; Dec. 1997; 10p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper presents the enhancements incorporated into TEST_PLAN, a commercially available flight test planning program, for the C-17 follow-on test program. TEST_PLAN is a software package for UNIX and VMS based workstation computers that allows Flight Test Engineers (FTE's) to plan and track flight test programs by mapping requirements to test points, flights, and flight test maneuvers. TEST_PLAN is integrated with the Oracle Relational DataBase Management System (RDBMS). Test points and requirements are stored in Oracle tables. The software provides automated tools that allows FTE's to query these tables to obtain lists of test points that can be assigned to maneuvers and flights to construct a flight test plan. The 417th Flight Test Squadron (FLTS) at the Air Force Flight Test Center (AFFTC), Edwards Air Force Base (AFB), funded four major enhancements to TEST_PLAN to support the C-17 follow-on flight test program. These enhancements are: (1) incorporation of the C-17 Test Parameter Requirements (TPR) database into TEST_PLAN; (2) implementation of an Instrumentation Discrepancy Report in TEST_PLAN; (3) integration of FrameMaker with TEST_PLAN to implement an automated flight test card generation facility; and (4) instituting a requirements compatibility matrix using Oracle tables and compatibility definitions provided by the administrator. The details of these enhancements are presented in this paper.

HELICOPTER CERTIFICATION-THE CHALLENGE OF TESTING UK APACHE

Finch, Roger S., Defence Test and Evaluation Organisation, UK; Advances in Flight Testing; Dec. 1997; 14p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

In July last year the UK Government announced the eagerly awaited decision on the UK Army's future Attack Helicopter (AH). The UK would purchase 67 WAH-64 APACHE helicopters, a derivative of the McDonnell Douglas Helicopters AH-64D Apache. The aircraft would be produced by GKN Westland Helicopters Ltd, as the Prime Contractor, with McDonnell Douglas Helicopter Systems as the Integrating Sub-Contractor. The WAH-64 would be fitted with a version of the Rolls Royce-Turbomeca RTM 322 engine, currently fitted to the UK's Merlin helicopter. The paper presents an overview of the emergent technologies being considered for the UK Apache, in particular a Defensive Aids Suite (DAS) and Helmet Mounted Displays (HMD). Ideas on a future handling qualities assessment are also presented. Before the first UK Apache arrives at Boscombe Down for clearance testing, the UK Test & Evaluation (T&E) community must develop the required clearance methodologies to evaluate the aircraft as a complete weapons system: preliminary work addressing this issue has already started. Clearance testing will, undoubtedly, make greater use of simulation, as well as placing more emphasis on joint testing

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE

with Industry. The challenge facing UK T&E is how to acquire the required test data with the minimum amount of testing to generate the evidence necessary for the aircraft's Military Aircraft Release (MAR).

The use of Modeling and Simulation (M&S) in the development of aerospace vehicles has evolved in step with the associated analytical and computational tools. During this evolution M&S has been balanced with necessary levels of flight testing as an integral part of the development process. Now, program managers are being urged to seek dramatic reductions in flight testing and to compensate with much greater reliance on M&S. A strong emphasis on fostering M&S development is essential to extend the aerospace state-of-the-art, and does hold promise for reducing development cost and cycle time. However, recent test programs do not provide confidence that M&S tools are presently of sufficient accuracy to permit a preponderant reliance on them at the expense of flight test. Premature dependency will introduce the risk that the system deficiencies usually found in flight testing will go undiscovered until after the vehicle is in production and operation. However, a concerted effort to research and correct demonstrated M&S failures to predict certain system characteristics will, given time, allow a complementary reduction in flight testing. This would allow the shifting balance of M&S with flight testing to be managed so as to keep program risks acceptable and ensure the high quality of resulting weapons systems.

IN-FLIGHT TESTS OF THE A300-600-ST 'BELUGA' ESSAIS EN VOL DE L'A300-600-ST 'BELUGA'

Destarac, Guy, Aerospatiale, France; Dec. 1997; 8p; In French; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In-flight tests of the A 300-600 ST 'Beluga', built by Aerospatiale and Daimler Benz Aerospatiale Airbus, were given to the Direction des Essais en Vol of the Branche Anions de l'Aerospatiale. This paper describes the installation of measures and the tools mounted on the first airplane for development and certification in-flight tests. It shows the means utilized for data processing and acquisition. The evaluation at the end of the test campaign shows that: the unexpectedly good behavior of the airplane in flight has compensated for the time required to resolve structural problems, the development of the charging system took longer than expected but did not delay the certification flights which were completed by the end of July 1995.

THE CERTIFICATION PROCESS OF THE OPHER SMART MUNITION ON THE AMX AIRCRAFT

Petraroli, E., Divisione Aerea Studi Ricerche e Sperimentazioni, Italy; Israeli, D., Elbit Systems Ltd., Israel; Advances in Flight Testing; Dec. 1997; 12p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The Italian Air Force (ITAF) has been seeking a low cost smart munition capable to attack vehicular targets with particular reference to armored vehicles and tanks. Low cost implies a guided weapon such as a laser bomb. The main objections to a laser guided weapon, such as those ones belonging to the Paveway family, derived from two intrinsic limitations: laser bombs require an illuminator (not a fire-and-forget weapon); and overall accuracy decreases dramatically with delivering energy. On the other hand, adoption of a missile would have increased both integration and procurement costs. So, it was decided to test the OPHER system in a different scenario with respect to that one which the system was originally designed for: (1) the Italian scenario, characterized by Mediterranean scrub, could have affected system performance in a different way with respect to Israeli desert; (2) the AMX can deliver weapons with an energy much lower than the F-4, on which this weapon has been employed in the Israeli Air Force; and (3) the AMX is equipped with a twin store carrier and the F-4 version of the OPHER system could not fit on it. The result of the successful testing and analytical work described in this paper led to the certification of the OPHER smart munition on the AMX for the Italian Air Force.

IN-FLIGHT TESTS OF THE RAFALE LES ESSAIS EN VOL DU RAFALE

Castagnos, Patrick, Dassault Aviation, France; Tourtoulon, Marc, Centre d'Essais en Vol, France; Dec. 1997; 22p; In French; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The in-flight tests of the RAFALE presented the opportunity to face difficult challenges, to initiate new testing techniques, and to adopt new organizational approaches. Since 5 years have elapsed since the 1st flight of the RAFALE C01 and the 4 prototypes have logged over 2300 flights, it seemed appropriate to conduct a comparison between in-flight tests as planned in 1990, and as they have in fact taken place up to the present. The two articles that follow undertake this analysis. The first is dedicated more specifically to the aspects of

costs, general objectives of the program and the status of technical refinements. The second is more centered on state-industry relations and optimizing skills and resources.

X-31A TACTICAL UTILITY FLIGHT TESTING

Friehmelt, Holger, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Guetter, Richard, Daimler-Benz Aerospace A.G., Germany; Kim, Quirin, Bundesluftwaffe, Germany; Advances in Flight Testing; Dec. 1997; 10p; In English; See also 19980035004; Sponsored in part by FMOD.; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The two X-31A were jointly built by Daimler-Benz Aerospace AG and Rockwell International. These German-American experimental aircraft were designed to explore the new realm of flight far beyond stall by employing advanced technologies like thrust vectoring and sophisticated flight control systems. The X-31A aircraft is equipped with a thrust vectoring system consisting of three aft mounted paddles to deflect the thrust vector in both pitch and yaw axes, thus providing the X-31A in this 'Enhanced Fighter Maneuverability' program with an agility and maneuverability never seen before. The tactical utility of the X-31A using post stall technologies has been revealed in an extensive flight test campaign against various current state-of-the-art fighter aircraft in a close-in combat arena. The test philosophy included both simulation and flight test. The tremendous tactical advantage of the X-31A during the tactical utility evaluation flight test phase was accompanied by a deepened insight into post stall tactics its typical maneuvers, impacts on pilot-aircraft interfaces and requirements for future weapons to both engineers and the military community. Some selected aspects of the tactical utility of the X-31A using post stall technologies unveiled by the International Test Organization are presented here.

THE EUROPEAN FIGHTER AIRCRAFT EF2000 FLIGHT TEST PROGRAMME OVERVIEW AND MANAGEMENT CONCEPT

Herr, Michael, Eurofighter Jagdflugzeug G.m.b.H., Germany; Butcher, Paul, Eurofighter Jagdflugzeug G.m.b.H., Germany; Dec. 1997; 12p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The Eurofighter 2000 (EF2000) Flight Test programme began with first flight in 1994. The aircraft will enter service at the beginning of the next century. In addition to the challenge of basic certification of the airframe with many different Air-to-Air and Air-to-Ground stores configurations, Eurofighter Partner Companies are also conducting testing to fully integrate the new developed Radar (ECR90) and Engine (EJ200). This paper constitutes a description of the EURO-FIGHTER Weapon System, the flight test programme management, an overview of the test programme plan and progress to date and discussion of unique challenges during testing. Up to now the EF2000 flight test programme has proceeded as planned and in-service certification should occur on schedule. The achievements reached so far

can be attributed to a well designed and built aircraft, a comprehensive test plan, a very reliable data system, and the personal efforts of thousands of people in four different countries.

THE V-22 OSPREY INTEGRATED TEST TEAM: A PERSPECTIVE ON ORGANIZATIONAL DEVELOPMENT AND TEAMING

VanderVliet, Gery M., Information Spectrum, Inc., USA; Price, Robert C., Price (Robert C.), USA; Advances in Flight Testing; Dec. 1997; 8p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In February of 1993 the US Navy's V-22 Osprey Program Management Team established a new way of managing its flight test program. This newly established flight test organization would be a departure from what the Navy Test and Evaluation (T&E) community had been used to, especially for an Acquisition CATEGORY One (ACAT I) program. It was that February that the V-22 Osprey Program Manager (PMA) would sign into contract the establishment of the Navy's first Integrated Test Team (ITT). The V-22 ITT, following in the path of the Air Force Combined Test Force (CTF) concept, would encounter and overcome many challenges. Soon after the V-22 ITT would be established, the Navy's F-18E/F program would follow suit with its own ITT, validating the worthiness of such an organizational concept. This paper discusses the conception, development, benefits, challenges, and lessons learned associated with the setup and operation of the V-22 Osprey ITT. This paper is written as a perspective from government ITT management only.

EMERGING MILITARY UNMANNED AIR VEHICLE SYSTEM CONCEPTS

Ramage, James K., Wright Lab., USA; Dec. 1997; 10p; In English; See also 19980201657; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Unmanned Air Vehicle (UAV) systems are evolving with unprecedented mission area capabilities. Next generation military UAV's offer the potential for achieving a revolutionary reduction in the total cost of conducting tactical air warfare. Exploiting the full potential of UAV's in terms of overall cost and mission capability is highly dependent on the ability to safely operate quasi-autonomously in a dynamic multi-vehicle combat environment. Continuous remotely piloted techniques and fixed pre-determined way point flight trajectory systems of the past, are giving way to more highly automated vehicle management systems to provide variable system integrity and user confidence. Development of multi-dimensional guidance and control, adaptive agent based flight management and information fusion technologies represent the essential enabling elements to permit safe and effective operational employment of unmanned strike aircraft. As the military community develops and matures the UAV technology base, commercial spin-off applications are also beginning to emerge, e.g. law enforcement, ground traffic surveillance, maritime patrols, and wide area telecommunication. The combined commercial and military UAV application trend will have serious implications with respect to civil airspace usage and associated vehicle certification requirements and standards.

This AGARD Advisory Report, was from the Flight Vehicle Integration Panel input to the AGARD study Aerospace "2020". This report examines the difficult questions of capability and affordability. The report focuses on the relevant trends in operational requirements and the technologies available to achieve these requirements. The report considers the affordability of forces as a main issue for the future. Topics include: a discussion in operational requirements, the technology available, advanced structures and materials, systems integration, types of air vehicles, and the affordability of forces. Technologies are assessed from the viewpoints of both potential capabilities and threats. Recommendations and conclusions are presented.

The Unmanned Tactical Aircraft is viewed by many as the centerpiece for affordable tactical air warfare in the year 2020 due to its potential for a revolutionary reduction in LCC and the fact that it embodies most of the Aerospace 2020 technology initiatives. Most of the technology for making the UTA effective as a weapon system is here today, but the technology for realizing its potential cost reduction remains to be developed.

HIGHLY MANEUVERABLE LETHAL VEHICLE (HMLV) CONCEPT
Palfalvy, George M., Naval Air Warfare Center, USA; Andes, David K., Naval Air Warfare Center, USA; Siegel, David, Office of Naval Research, USA; Jul. 1998; 6p; In English; See also 19990007836; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The paper presents interim results of a technology feasibility study of an unoccupied, armed, reusable, semi-autonomous air weapon system- the Highly Maneuverable Lethal Vehicle (HMLV). The HMLV concept that is currently being studied nominally has the following characteristics: (1) Acceleration capability greater than that of any manned aircraft; (2) Sensors, sensor processing, automatic target recognition algorithms and reasoning/decision-making algorithms to allow it to operate almost completely autonomously; (3) A variable-bandwidth, jam-resistant data-link to communicate images to an offboard controller; (4) Lightweight, inexpensive, but precision guided and highly lethal, weaponry to prosecute air and surface targets; and (5) Airborne refueling capability. The study's goal is to examine applicable technologies and determine where they are lacking so that research funding can be properly focused. Interim results indicate that: (1) High-g airframes can be built (range and loiter capability for these airframes may be an issue); (2) Turbojet engines that can withstand the high-g environment can be built; (3) Sensor and signal-processing research is progressing at a rate that will produce sufficient capability in the near future; (4) The high-g capability of the HMLV, combined with a simple infrared countermeasure, will allow it to evade most threat missiles; and (5) Advances in computational algorithms, including ATR, will be required.

SYSTEM INTEGRITY CONSIDERATIONS FOR UNMANNED TACTICAL AIRCRAFT

Scheithauer, D., Industrieanlagen-Betriebsgesellschaft m.b.H., Germany; Wunderlich, G., Industrieanlagen-Betriebsgesellschaft m.b.H., Germany; Jul. 1998; 12p; In English; See also 19990007836; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

In general, unmanned aerial vehicles (UAVS) and Cruise Missiles (CM) have demonstrated their operational value in the limited conflicts of the last years. This experience and technological advances promise similar successful results for more sophisticated Unmanned

Tactical Aircraft (UTA) covering a wider range of airborne mission roles. Throughout this publication the term UTA will be used in favor of the term uninhabited combat aerial vehicle (UCAV). In this paper UTA concepts are evaluated with respect to system integrity. In a first step mission scenarios are analyzed with respect to the hostile threats an UTA will encounter. These external threats together with internal threats affecting reliability and system safety are the reference for the evaluation of the required integrity levels. On the basis of a generic system architecture essential and non-essential functions are considered. The assessment led to the result that UTA will be quite complex. This will have a major impact on the life cycle costs according to the experience with manned aircraft programs. However, compared with manned aircraft weapon systems UTA life cycle costs will be lower due to fewer operating costs.

UNCONSTRAINED MANEUVER AIR VEHICLE: A CONFIGURATION DEVELOPMENT

Shenk, Barth W., Wright Lab., USA; Jul. 1998; 10p; In English; See also 19990007836; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Maneuverability-based sizing of a notional, unmanned air vehicle is presented with spin tunnel test results of a resultant configuration. Sustained load factor and roll acceleration were traded against wing loading, thrust-to-weight ratio and aspect ratio for a notional air-to-air combat mission. Prospective turn and roll performance goals were developed for an unmanned fighter, and physical limitations of thrust matching between cruise and maneuver power requirements was studied. The resulting configuration characteristics indicate that optimization of this class of vehicle requires development of inertial optimization methods and structural design methodologies for instantaneous, dynamic loads.

SYSTEM LAYOUT OF AN UNMANNED HIGH ALTITUDE AIRCRAFT FOR CERTIFICATION AND FLIGHT IN CIVIL AIRSPACE

Papachristofilou, I., Papachristofilou (I.), Greece; Kaempf, P., Daimler-Benz Aerospace A.G., Germany; Wagner, O., Technische Univ., Germany; Jul. 1998; 8p; In English; See also 19990007836; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Several unmanned air vehicles (UAVs) are currently in operation or under development, and predictions for the future indicate an expansion in the tasks that will be covered by UAVs. With missions conceivable both in the civil as well as military sectors, UAVs are expected to be procured and operated in increasing numbers in the immediate future. However, besides the technical challenges associated with unmanned flight, the issues of certification and rules of operation of unmanned aircraft in non-restricted airspace need to be addressed. Flights of unmanned aircraft are currently taking place within reserved airspace with only few exceptions where UAVs have been allowed to enter open airspace under special precautions. The potential of unmanned aircraft can only be exploited if such restrictions are lifted and they are certified to operate along manned aircraft. To reach such a point, formulation of explicit certification requirements on the system design of the aircraft is required, as well as a series of flight tests to validate the concept of safe use of unmanned aircraft in non-restricted airspace. Although such regulations do not exist at the moment, airworthiness and air traffic control authorities have already started examining the issues involved and are expected to issue guidelines covering unmanned flight in the near future. Based on information available from the above mentioned authorities, the main characteristics of those regulations can be described at the present time. Moreover, the implications on the system design of unmanned aircraft can be highlighted, showing the parameters that are to influence future designs. In our view the least complicated route to the operation of unmanned aircraft in civil airspace can be explored with a subsonic high altitude reconnaissance platform. Here the relocation of the pilot to a ground station offers the highest benefits, creating a strong ratio-

nale for the development of such a craft. At the same time, only a limited number of additional subsystems are necessary to facilitate flight in open airspace, which will be demonstrated by means of a recently concluded conceptual design of an unmanned high altitude aircraft.

The concept of using a hypersonic drone aircraft operating at very high altitude is analyzed. One example of an operational flight is obtaining an important class of information which is difficult to obtain by other means. Of equal importance, the mounting of sensors is strongly connected with the size of the vehicle, and must, by this standard, be considered in the preliminary project for finalizing the main options.

This report is a guide to methods of representing in a flight simulator, the stability and control of an aircraft on the ground. It updates an earlier publication, AGARDograph 285, in the light of simulation technology improvements over a ten year period. Emphasis is placed on the modeling of the vehicle dynamics, and on the modeling of the tire forces generated by the runway surface. Areas are identified where some current simulators are deficient. The different needs of pilot-in-the-loop and non-real-time simulations are discussed, and topics for further research are identified.

PILOT TESTING IN VIRTUAL ENVIRONMENTS

Weeks, Joseph L., Advisory Group for Aerospace Research and Development, France; Siem, Frederick M., Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 11-12; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

In the 1980's, applicants to undergraduate pilot training were tested on verbal and quantitative achievement while seated at a desk with pencil and paper. In this decade, applicants are also tested on information processing performance and psychomotor performance while seated at a personal computer with joy sticks and a keypad. By 2020, applicants to undergraduate pilot training, could don goggles and data gloves and enter a virtual environment for the measurement of leadership and team work. Major improvements in pilot testing have been achieved by augmenting the measurement of verbal and quantitative achievement with the measurement of information processing and psychomotor performance. A large evidentiary basis has been established to demonstrate that pencil and paper selection tests measure the abilities important for piloting an aircraft. The addition of measures of information processing and psychomotor performance increment the validity of pencil and paper testing by more than fifty

percent. The next major improvement in pilot testing could be accomplished by the measurement of leadership and team work by using virtual reality computer technology.

ROTORCRAFT 2020

Blake, Bruce B., Advisory Group for Aerospace Research and Development, France; Tischler, Mark B., Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 40-43; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

Rotorcraft have played a key role in all recent conflicts, as witnessed by use of AH-64's in the opening days of the Gulf War to neutralize Iraqi border defense, and the continuing rotorcraft role in regional conflicts including Somalia, Iraq and Bosnia. Emerging rotorcraft systems coming on-line in the NATO countries during the coming decade include the Comanche, Tiger, NH-90, EH101, and V-22. These systems will exhibit improved capabilities in weapons integration, all-weather operations, and will have increased performance and agility. Future systems envisioned for the 2020 timeframe will make full use of active control technology and smart structures to reduce noise and vibration and increase agility in a care-free maneuvering vehicle. Advances in avionics and GPS technology will be integrated in an advanced glass cockpit that allows for increasingly accurate navigation and weapons delivery in all weather conditions with a tolerable pilot workload. Increased use of integrated modular avionics architecture will improve mission reliability, facilitate maintenance and improve supportability. Further, the full use of unmanned air vehicle (UAV) technologies in a combined manned-unmanned force structure will dramatically improve mission effectiveness without exposing the pilots to unnecessary risks in hostile territory. This paper explores the vision for future rotorcraft technologies as an important component of AGARD Aerospace 2020.

Integrated Airframe Design Technology is an important element of a number of activities required to improve the business performance of Aircraft companies worldwide. The customers require more reliable products at an affordable price that perform to specification and are easy to support in service. The time required to design and build an aircraft needs to be reduced and also an environment created whereby all parties involved can work together to influence the development of the design at an early stage. This approach coupled with enhanced visualization and simulation of both the functional and physical elements of the product design will enable modifications to be implemented as part of the design process before the start of manufacturing/

build. Thus the need for changes to be carried out during and after production build will be significantly reduced and will result in impressive savings in costs. Integrated Airframe Design Technology provides the basis for this new environment to be developed.

MAINTENANCE-FREE AIRCRAFT

Welburn, Steve, Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 126-127; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

Although the ultimate aim of a maintenance-free aircraft may never be achieved, the Aerospace 2020 report highlights the huge cost savings that would result from a substantial reduction in aircraft maintenance costs. The route to achieve these savings has to be via the correct specification of reliability targets for the next generation of aircraft procurement. In particular, reliability throughout the complete mission should be specified as a prime operational performance characteristic of new equipment as it is the ultimate verification of the effectiveness of any weapon system. However, as new equipment to meet new missions becomes increasingly complex, the specification of mission reliability, and the subsequent assurance that the required reliability has been delivered, becomes extremely difficult. Life Cycle Costs (LCC) need to be addressed from the earliest days of a project, in feasibility studies, and followed through into the design and acquisition stage since 90% of LCC may be determined by the decisions made before production of a new weapon systems begins. This paper highlights the emphasis now being placed on maintenance free operating periods for aircraft rather than the traditional approach of assessing mean time between failures for individual equipment.

AGEING AIRCRAFT

Sampath, Sam G., Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 128-130; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

Aging Aircraft concerns have dramatically escalated in military and civilian quarters alike during the past few years. The percentage of aircraft that are being operated beyond their design lives is ever increasing. As of 1993, approximately 51% of the aircraft fleet in the US Air Force (USAF) was over 15 years old and 44% was over 20 years old. Yet, some aircraft models that have already served NATO for 30 years or more may need to be retained for another two decades. Due to NATO's changing role which includes peace keeping missions remote from home bases, the requirement of unimpaired high operational capacity, higher utilization of its air fleets, and budgetary stringency's, prospects are for aging aircraft problems to continue to become more acute. Aging Aircraft has several connotations. Among them: (a) technological obsolescence, (b) system upgrades, (c) changing mission requirements unanticipated during design specification and development, (d) the specter of runaway maintenance costs, (e) decreased safety, (f) impairment of fleet readiness, (g) unavailability of home depot facilities. If there is one common denominator among these connotations it is that the cost of operating aging aircraft can be very high. However, technical solutions will be available to fleet managers to deal with the problem of aging aircraft in 2020.

SMART STRUCTURES AND MATERIALS IN AEROSPACE APPLICATIONS OF NEXT GENERATION

Boller, Christian, Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 133-140; In English; See also 19990014353; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

Development in disciplines such as sensing technology, computation, control, micromechanics, materials including processing and many others have made significant progress during the past decades. This progress has been mainly possible through an in-depth analysis of the different aspects in these disciplines. To consequently take more advantage of this progress a synergy between these different disciplines has to be established, resulting in what has been termed to be smart materials and structures. Smart (alternatively; active, adaptive, multifunctional or intelligent) materials and structures is, briefly explained, the integration of sensing and actuation elements into a structure or even more ambitiously into a material, with sensor actuator being linked by a controller. Materials actually favored for integration include optical fibers and piezoelectric materials with respect to sensors, piezoelectric/electrostrictive materials, shape memory alloys and electro-rheological fluids with respect to actuators and microprocessors, neural networks, fuzzy logic and various types of signal processing with respect to control. Since performance of aircraft and spacecraft has progressed in a sequence of steps in the past, smart materials and structures technology can thus be considered to be the next step in enhancement.

AIRCRAFT INSTRUMENTATION

19950026076 NASA Langley Research Center, Hampton, VA, United States

A HIGHLY RELIABLE, HIGH PERFORMANCE OPEN AVIONICS ARCHITECTURE FOR REAL TIME NAP-OF-THE-EARTH OPERATIONS

Harper, Richard E., Draper, Charles Stark Lab., Inc., USA; Elks, Carl, NASA Langley Research Center, USA; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 14 p; In English; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

An Army Fault Tolerant Architecture (AFTA) has been developed to meet real-time fault tolerant processing requirements of future Army applications. AFTA is the enabling technology that will allow the Army to configure existing processors and other hardware to provide high throughput and ultrahigh reliability necessary for TF/TA/NOE flight control and other advanced Army applications. A comprehensive conceptual study of AFTA has been completed that addresses a wide range of issues including requirements, architecture, hardware, software, testability, producibility, analytical models, validation and verification, common mode faults, VHDL, and a fault tolerant data bus. A Brassboard AFTA for demonstration and validation has been fabricated, and two operating systems and a flight-critical Army application have been ported to it. Detailed performance measurements have been made of fault tolerance and operating system overheads while AFTA was executing the flight application in the presence of faults.

A HELMET MOUNTED DISPLAY FOR NIGHT MISSIONS AT LOW ALTITUDE UN VISUEL DE CASQUE POUR LA MISSION DE NUIT A BASSE ALTITUDE

Cursolle, Jean-Pierre, Sextant Avionique, France; Leger, Alain, Sextant Avionique, France; Leppert, Franck, Sextant Avionique, France; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 10 p; In French; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The achievement of air to ground mission in a complex operational context, with bad meteorological conditions and, moreover by night is a very demanding task for the pilot. This mission requests a high situation awareness which can only be reached with specific, accurate and reliable means, such as sensors, displays or controls, perfectly integrated in the aircraft system. The mission can be successfully realized thanks to sensors performances. But, the use of FLIR or I(sup 2)T depends on a lot of conditions such as weather with

bad effects on the efficiency. So images must be enhanced with symbols to be fully exploitable. Furthermore, the sensors have to be fully integrated, the efficiency depending on the interfaces such as displays and controls. The third Generation Helmet Mounted Display is an answer to this requirement but has to be fighter pilot customized. The conference will include a few operational requirements recall, the Sextant Gen 3 HMD description and will highlight the first symbology results issued from a ground simulation assessment.

FEDERATED FILTER FOR FAULT-TOLERANT INTEGRATED NAVIGATION**

Carlson, Neal A., Integrity Systems, Inc., USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 265-280; In English; See also 19960003395

Contract(s)/Grant(s): F33615-87-C-1520; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper describes federated filter applications to integrated, fault-tolerant navigation systems. The federated filter is an optimal or near-optimal estimator for decentralized, multisensor data fusion. Its decentralized estimation architecture is based on theoretically sound information-sharing principles. Federated filters consist of one or more sensor-dedicated local filters, generally operating in parallel, plus a master combining filter. The master filter periodically combines (fuses) the local filter solutions to form the best total solution. Fusion generally occurs at a reduced rate, relative to the local measurement rates. The method is well suited to real-time system implementation, and can provide significant improvements in data throughput, fault tolerance, and system modularity. This paper discusses federated filter applications to integrated navigation system in terms of operating modes, accuracy, fault tolerance, computational efficiency (throughput), and real-time system features. Numerical simulation results are presented to demonstrate federated filter performance characteristics.

AEROSPACE NAVIGATION SYSTEMS REQUIREMENTS FOR FIXED WING AIRCRAFT

Bedoya, Carlos A., McDonnell-Douglas Aerospace, USA; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 330-380; In English; See also 19960003395; Copyright; Avail: CASI; A04, Hardcopy; A04, Microfiche

The purpose of this paper is fourfold: (1) to provide the radar with a status report on the state-of-the-art of navigation system technology as applied to fixed wing aircraft; (2) recommend a disciplined systems engineering process to be used in determining navigation system requirements as they relate to navigation, sensor cueing and targeting as well as weapon requirements; (3) examples of how to functionally decompose each aircraft and analyze its mission requirements into the navigation system requirements; and (4) a typical set of requirements for a fixed wing aircraft. The results will allow the navigation systems designer to have a process he can follow in determining or verifying the requirements of a particular application as well as a baseline set of requirements.

TACTICAL COCKPITS: FLAT PANEL IMPERITIVES

Adam, Eugene C., McDonnell-Douglas Aerospace, USA; Situation Awareness: Limitations and Enhancement in the Aviation Environment; Jan. 1996, 9-1 - 9-7; In English; See also 19960023107; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

A cockpit revolution is in the making. Many of the much bally-hooded, much promised, but little delivered technologies of the 70's and

80's will finally come of age in the 90's just in time to complement the data explosion coming from sensor and processing advances. Technologies such as helmet systems, large flat panel displays, speech recognition, color graphics, decision aiding and stereopsis, are simultaneously reaching technology maturities that promise big payoffs for the third generation cockpit and beyond. The first generation cockpit used round dials to help the pilot keep the airplane flying right side up. The second generation cockpits used Multifunction Displays and the HUD to interface the pilot with sensors and weapons. What might the third generation cockpit look like? How might it integrate many of these technologies to simplify the pilots life and most of all: what is the payoff? This paper will examine tactical cockpit problems, the technologies needed to solve them and recommend three generations of solutions.

Modern military aircraft rely heavily on highly complex electronic systems to make them effective. These systems can compromise up to 80% of the cost of the aircraft. As new systems are developed, numerous tests are needed to provide feedback in the iterative design process and to ensure that the design parameters are met. This AGARDograph is an attempt to present the rudimentary knowledge necessary for a test pilot or engineer to develop and execute a cost effective, quick test of a modern avionics system.

ADVANCED AVIONICS ARCHITECTURES: WHERE ARE WE GOING?

Domae, T. P., Northrop Grumman Corp., USA; Logan, H. L., Northrop Grumman Corp., USA; Viney, J. E., Northrop Grumman Corp., USA; Advanced Architectures for Aerospace Mission Systems; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

We will explore the question of where avionics architectures are today, considering the Joint Strike Fighter and the evolution of open system approaches from the PAVE PACE and PAVE PILLAR programs of the 1980's. The recent work extends today's notions of a unified software and hardware approach to core processing and a common interconnect between architectural elements, not only to sensor or signal processing, but toward the apertures themselves and the system development environment. We shall take a broad view of the problem that includes RF electronics, interconnect, operating systems and application software development, processing hardware, and the system development environment itself. The architectural

extensions discussed here are made in the context of the basic long term technology trends of more digital sensor processing and preprocessing, higher performance analog-to-digital converters, lightwave technology for both signal distribution and routing, and software structures that reduce development expense, while increasing the supportability and portability of applications software. Future RF electronics modules will be waveform independent and support multifunction apertures in a given spectrum for a selected bandwidth, with a strong impact on affordability since the RF sensors and their associated electronics correspond to some 70 percent of avionics fly-away cost. We will show how decoupling the explicit interactions of various system elements simplifies development and system integration by removing unwanted design dependencies and providing upgrade paths for cost effective technology insertion, with minimum system breakage. These techniques will be used to implement the principles of modularity, scale up, and ability to upgrade that have become part of the today's open system approaches and will be even more important in the future as the opposite poles of capability and affordability govern both new systems and upgrades. A coherent integrated architecture that promises more affordable development, implementation, and support is presented as the answer to the question, 'Where are we going?'

MODULAR AVIONICS SYSTEM ARCHITECTURE DEFINITION IN THE EUCLID RESEARCH AND TECHNOLOGY PROGRAMME 4.1: METHODOLOGY AND RESULTS

Marchetto, A., Alenia Aeronautica, Italy; Jul. 1997; 12p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The European Cooperation for Long Term in Defense (EUCLID) Research and Technology Programme (RTP) 4.1 'Modular Avionic Harmonization Study' is a joint programme carried out by France, Germany, Italy, Netherlands, Spain and United Kingdom, aiming to harmonize modular avionic concepts among the aforementioned nations, thus preparing a common European basis for the future development of modular avionics platforms, taking as reference the 2005/2010 in service date time frame. The work has been developed through five work packages, dedicated respectively to General Requirements for Modular Avionics, System Architecture Definition and Risk Assessment, Technology Programmes, Modular Avionics Support Facilities, Identification of a Roadmap for Modular Avionics. This paper presents an overview of the methodology that has been adopted to come to the definition of a modular avionic system architecture which is capable to satisfy a defined set of functional requirements, in presence of technical constraints of various nature resulting from technology assessments carried out during the programme. The paper discusses the following subjects: The different functional areas to be covered by an avionic system tailored on an envelope of operational requirements. The different categories of functional/physical elements which compose the modular system. Those requirements, among the set of driving functional requirements taken as reference in the course of the study, whose impact has been so relevant to drive or condition the architectural study. Technical requirements and constraints associated to the physical elements having a direct impact on the system architecture model. The basic characteristics and an outline of the proposed architectural model, how it has proceeded from the above functional/technical requirements, and how it incorporates important features, such as an adequate capability to tolerate faults by reconfiguration and to perform data fusion at various levels. Limits of the architectural study carried out.

WHEN DO ADVANCED AVIONICS ARCHITECTURES MAKE SENSE FOR UPGRADING AGING AIRCRAFT?

Krueger, C. H., Wright Lab., USA; Venner, R., Wright Lab., USA; Jul. 1997; 10p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

With the dramatic reduction in defense spending in NATO countries, it is quite clear that there will be few new military aircraft for

perhaps many years. A consequence is that there will be widespread use of current aircraft to satisfy future military mission requirements. One of the most cost-effective means for improving the capability of a military aircraft to deal with new threats and mission requirements is to upgrade the performance of the avionics suite. However, current federated avionics subsystems are weapon-system unique, have limited capability and life and may not support new functional requirements. In addition, the cost of performance upgrades for federated avionic suites are prohibitive, particularly in terms of the budgets available. Integrated, modular avionics technologies offer substantial potential for improving the reliability and reducing the cost/weight volume per function for adding new functional capability. Integrated, modular avionics are normally considered for new aircraft, but there is some evidence that they may have potential in some circumstances for older aircraft as well. This paper examines several military aircraft applications and discusses the circumstances where the retrofit of an advanced avionics architecture may be preferred to more conventional approaches. The major consideration is cost per function. The paper will show that the advanced architecture is a clear winner as the number of functions is significant in terms of the level of integration required with other subsystems. It is very difficult to determine with even coarse precision the costs of various approaches, but certain trends are apparent. Not too surprisingly, the dominant acquisition cost is not the avionics equipment, but the cost of installing and integrating the equipment into the aircraft together with the cost of testing, documentation and training.

THE FUTURE OF AVIONICS ARCHITECTURES

Morgan, D. Reed, Wright Lab., USA; Jul. 1997; 14p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A look into the future of avionic architectures over the next twenty years is presented by extrapolating past evolutionary trends, projecting future military needs and projecting the availability of advanced architectural building blocks. The basis for this forecast is drawn from the hypotheses that: (1) the physical and functional attributes of architectures evolve, even though the building block technologies often undergo revolutionary changes; hence, extrapolation of past architectural trends provides a good 'first cut' look at the future, (2) basic changes in architecture are driven by network bottlenecks resulting from the application of advanced technology building blocks that are used to improve situation awareness; hence an understanding of forces driving improvements in situation awareness and what devices future architects will have at their disposal helps frame the processing and interconnect requirements (and hence the architecture) and (3) cost containment, even cost reduction of avionics systems, will be the dominant driver for future architectures; hence, any form of physical or functional integration that reduces cost also helps define future architectures. Conclusions drawn from this paper are: (1) architecture changes resulting from avionics updates will continue to be evolutionary, with new building blocks and network designs 'grown onto' the existing infrastructure, (2) architectural extensions for retrofits will take the form of 'bridging' network interface circuitry that will interconnect advanced COTS-based networks and processors, (3) the drive for improved situation awareness will force architectures to increasingly support signal processor-based networks that will be dominated by several gigabit/second streaming data; as a result, switch-based, point-to-point links will be the primary means of system-level interconnections, with bus-based networks being used mostly for control and message passing at the backplane level, (4) for the first time, the application of new photonics-based building blocks to new avionics designs will eventually allow the avionics architect the design freedom to physically and functionally locate computing assets at space-available locations without performance penalty, (5) highly digital, 'functionally integrated, physically distributed' systems will emerge, with the co-habitation of RF analog and digital pre-processing, signal and data processing modules existing within the same module-based enclosure. A physically distributed, unified network will result, with a unified interconnect network across RF, IF, data and signal processing modules, (6) analog photonics will emerge to challenge RF electrical signal distribution,

filtering and frequency conversion functions, (7) the digital boundary will move closer to the RF apertures; digital CNI (up to 2 GHz) systems and a mostly digital-based radar warning and radar systems will eventually replace more costly analog designs, X) within the next 15-20 years, a new 'fourth generation' architecture will emerge that will embody the features described above. The dominant feature of this projected architecture is the similar interconnect structure that both analog and digital avionics will assume. As a result of the increasing digitization of analog functions and the availability of high speed networks, the classical physical boundaries of avionics will almost vanish, (9) architectures will be driven and constrained by the mandate that designs be made open and commercial-based to the greatest extent possible. This trend will profoundly affect future architectures in that network protocols, processors and software operating systems will likely change with time. Coping with this changing environment will require the expanded use of design tools, descriptive design languages and programmable interfaces. Future architectures must be designed for change at the outset.

TECHNOLOGY TRANSPARENCY IN FUTURE MODULAR AVIONIC SYSTEMS

Edwards, R. A., British Aerospace Defence Ltd., UK; Connan, C., Dassault Aviation, France; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Affordability is a key driver for future weapon systems, and it is generally accepted that integrated modular avionics (IMA) can make a major contribution to the reduction of acquisition and support costs. However, the technologies upon which IMA depends are evolving rapidly, and there is a danger that emerging IMA standards and systems under development will become obsolete over timescales which are short compared to military programme lifecycles. This paper suggests that steps can be taken to mitigate the impact of obsolescence on complex avionics systems by ensuring that technology transparency is established as a key architecture characteristic, and is tackled from the outset in standardization activities and in system design. The importance of technology transparency is a consequence of the rate of technology development in relation to the long system life-cycle for military projects, and the need for interchangeability and backwards compatibility of new building blocks in 'old' systems in order to reduce life cycle costs (LCC). Examples of how technology transparency can be achieved are given for the hardware, software and data networks domains. Key areas for long term 'open system' interface standards which support technology transparency are identified, based on information previously released from the Allied Standard Avionics Architecture Council (ASAAC) standardization program. The implications of system level issues (safety, security, qualification, etc.) and the drive to exploit Commercial Off The Shelf (COTS) technology are explored, and the need to consider technology transparency for system design tools is established. The main conclusion is that, whilst many regard technology transparency as the 'Holy Grail' of IMA, practical solutions are possible in a number of areas and must be pursued vigorously through programmes such as ASAAC if LCC benefits are to be maximized.

This paper reports on the refinement, demonstration and validation of a number of key concepts for Integrated Modular Avionics

(IMA), as performed under the IMA Demonstrator programme. For the communication network, software architecture, and fault management areas, selected aspects of the concepts were refined, and implemented on a demonstration platform. This platform, termed the IMA Demonstrator, is a tool for investigating and evaluating IMA issues, and has been constructed largely from commercial off the-shelf components. In the IMA Demonstrator, the communication network is implemented by a functional prototype of the Matrix Switched Network. The software architecture of the IMA Demonstrator includes functional prototypes of the communication system and the fault management system. The IMA Demonstrator and its functional prototypes have been used to validate the relevant IMA Concepts.

SIGNATURE AVIONICS: SIGNATURE OPTIMISED OPERATING OF A STEALTH AIRCRAFT

Hurst, P., Daimler-Benz Aerospace A.G., Germany; Knappe, P., Daimler-Benz Aerospace A.G., Germany; Benninghofen, B., Daimler-Benz Aerospace A.G., Germany; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Stealth design is one design principle for next generation combat aircraft. The effort in this area have a long history at the Daimler-Benz Aerospace (Dasa), formerly MBB, e.g. the Lampyridae project in the early 80's. Operational studies have shown that the introduction of stealth design will increase the survivability of combat aircraft significantly, especially against airborne threats. Yet the effective use of critical signatures during a mission and the matching of tactics to stealth features require the development of an adapted avionics. This adapted avionics - signature avionics - will not compromise the stealth design, take direct advantage from the stealth characteristics, and utilize the stealth properties via an integrated tactical mission control. To transform this idea into an applicable format suited for the implementation in aircraft avionics systems, a functional breakdown in individual functions, prototyping and performance analysis of these functions, turns out to be necessary. The feasibility of this approach has been proven on the signature avionics function 'fly by signature' as an example.

With knowledge of persistent data communication traffic patterns offered to an avionics data network, modifications to the routing through the network can be made to improve total throughput and bound the latency of packets. The Multiservice Switch (MSS) is such a route-optimizing switch for streaming sensor data. The MSS has two switching fabrics. packet switching and circuit switching. The packet-switching fabric routes small control and data packets between switch ports. The circuit-switching fabric uses a crossbar to physically connect ringlets, which reduces the workload on the packet-switching fabric long data streams between the ports. An implementation of the MSS is described which uses commercial-off-the-shelf (COTS) components. A simulation model was developed to show the benefits of the MSS under standard avionics workloads. The results of the MSS indicate distinct advantages in terms of performance, price, and power consumption over other conventional switch and network topology designs.

SIMULATION OF A CELL SWITCHED NETWORK FOR THE CONTROL OF A SWITCH MATRIX IN A HIGH-SPEED AVIONICS NETWORK

Aupers, David A., National Aerospace Lab., Netherlands; Heerink, Gerald J., National Aerospace Lab., Netherlands; Wellink, Steven, National Aerospace Lab., Netherlands; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper describes the research and experiments carried out by the National Aerospace Laboratory (NLR) in the field of high-speed interconnection systems for modular avionics. The research has been carried out in the EUCLID/RTP4.1 framework. The avionics network that was modelled and simulated was an optical switch matrix under control of a cell switched network. The optical switch matrix offers the avionics system circuit switched, uni-directional, point-to-point connections. A bandwidth of 2 Gbps is projected. The main purpose of the matrix is to connect sensors producing high data rates, such as an attack radar in fighter aircraft, with the core avionics processing cluster. The cell switched network - in this case Asynchronous Transfer Mode (ATM) - controls the optical switch matrix and provides data transfer at lower data rates, file transfer, and status messages. The simulation model operated ATM at 149 and 622 Mbps. The primary objective of our research was to assess ATM as a data link layer for a control and message network in an avionics data network. The computer-based tool to model the network was SES/Workbench.

A review of the modular avionics concepts is presented in light of DOD's mandate to change the military's acquisition process and the recent delivery of advanced modular processing systems developed to meet the demands of the next generation avionics. Future trends - in avionics are discussed along with how this will impact the modular standards just now being implemented. Modular avionics is the most dominant feature of our advanced avionics systems. Initially mandated because of the projected cost advantages, modular avionics also provides significant performance potential. Modular avionics is characterized by configurations that partition the system into building blocks that feature integration, modularity, and commonality. The main focus of these concepts is initially being applied to the digital core avionics for which the F-22 Common Integrated Processor is a powerful and innovative realization. The USAF PAVE PACE and NASA programs extended the current concepts further and the initiatives to integrate commercial-off-the-shelf (COTS) technology has fostered innovative solutions to improve increased availability at reduced costs. Functions within the aircraft will become more integrated requiring innovative approaches to the management of the computer resources and distribution of information.

A MODULAR SCALEABLE SIGNAL PROCESSOR ARCHITECTURE FOR RADAR AND EW APPLICATIONS

Keller, H. P., Daimler-Benz Aerospace A.G., Germany; Rabel, R., Daimler-Benz Aerospace A.G., Germany; Schmitt, K.-P., Daimler-Benz Aerospace A.G., Germany; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Daimler-Benz Aerospace, Ulm has developed the Advanced Programmable Signal Processor (APSP), a modular, scaleable and programmable multi-Gigaflop machine based on studies sponsored by GMOD. The modular architecture allows an easy tailoring to quite different requirements in signal processing and pattern recognition for Radar, Sonar, Electro-optical sensor applications, e.g. from small non-coherent radar and EW systems up to sophisticated airborne multi-mode pulse doppler radars or complex ground or ship based multi-

channels radars. From an architectural point of view, the APSP comprises clusters of single chip floating point processors (Texas Instruments TMS320C3x [1] digital signal processor which can perform 32-bit floating point calculations at a 60 Megaflop rate), special partially programmable modules (based upon off-the-shelf VLSI-chips), multipurpose memory modules and multipurpose interface modules. The APSP comes with comprehensive Software and Tools including the real time multiprocessor operating system APOS. The modularity and scalability in Hardware and Software offers the possibility to tailor the signal processor performance to the application, while preserving options for growth potential. Furthermore modifications in the processing algorithms are done via software changes, without costly hardware redesign. This article focuses the major aspects of the APSP in Hardware, Operating System and Software Tools and shows the implementation of a small and a high performance application.

SENSOR FUSION FOR MODERN FIGHTER AIRCRAFT

Taubenberger, K., Elektroniksystem- und Logistik G.m.b.H., Germany; Ziegler, J., Daimler-Benz Aerospace A.G., Germany; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Sensor Fusion has become important for fighter aircraft in order to improve the air picture with respect to the displayed area of all sensors, the precision of target's kinematic data, the confidence in the target's identity, and to support the management of the sensors. The paper investigates system architectures of existing and future sensors. Based on a Bayesian fusion approach, the benefits and constraints of data throughput, accuracy and track consistency is shown. The results of simulation runs with radar, IR and ESM sensor models together with a data link network are presented.

The Department of Defense is being driven to use Commercial Off-the-Shelf (COTS) hardware and software in order to reduce the overly complex and unnecessary practices of using military standards and specifications while reducing costs. There are a variety of issues related to the use of COTS hardware and software components in military avionics systems that have an impact in the architectures. Avionics packaging, cooling, networks, processors, and software languages are just a sample of the areas affected by the use of COTS. A number of steps must be taken by weapon systems managers to ensure they have a strategy in place to meet the challenges brought on by COTS technologies.

AN APPROACH TOWARDS INTEGRATION OF A MODULAR CORE AVIONICS SYSTEM KERNEL

Grasshoff, M., Daimler-Benz Aerospace A.G., Germany; Foerster, M., Daimler-Benz Inter Services, Germany; Jul. 1997; 14p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Daimler-Benz Aerospace (Dasa) Military Aircraft Division has set up an experimental avionic system with modular structure using VMEbus based hardware components and a commercially available operating system (OS) as common OS. Since commercially available realtime OS's do not fulfill the requirements for future avionic systems, System Management Software (SYMS) has been developed. SYMS enables the communication between different processor modules and

their co-operation. This is the presupposition for fault management and reconfiguration management within the whole core system. The reconfigurability of the experimental system has been demonstrated. The source code of SYMS has been fully written in Ada. Small sized interfaces to the hardware and to the OS support easy adaptation to different environments of hardware and or OS. Applications of the whole core system are controlled separately by SYMS Tables (Blueprints). The approach supports developing portable and reusable application software. The flexibility of SYMS enables the demonstration of different standards and their capabilities within different integrated systems. Currently, this work is of interest in view of the Allied Standard Avionics Architecture Council (ASAAC) demonstration programme, planned for the ASAAC Phase 2. Flight capable derivatives of the experimental system can be used in different experimental flight programmes. Information about a modular computer to be flown within an experimental flight programme is presented.

LOW-LEVEL FLIGHT CAPABILITY OF A FUTURE MILITARY TRANSPORT AIRCRAFT BASED ON COMMERCIAL AVIONICS
Kricke, K. Dieter, Daimler-Benz Aerospace A.G., Germany; Schaefer, Dirk, Daimler-Benz Aerospace A.G., Germany; Jul. 1997; 10p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

There is a need for a new military transport aircraft, which can cope with the operational requirements to improve the current air transport forces of the European countries to satisfy tactical, logistic and future operations, at the beginning of the next century. Significant requirements, which relate to the avionics and mission systems, are for instance: low-level flight capability and board-autonomous approach and landing capability enabling adverse weather operations by day and night. This paper describes a system concept for low-level flight capability based on commercial avionics as used in AIRBUS aircraft. First, the essential functions and features of the flight control and flight guidance system are highlighted. Then, the additional functions and system elements related to controls/displays and operational modes, which are required for low-level flight, are discussed. Finally, the first results of a demonstration and pilot evaluation performed in the flight simulator a DAIMLER-BENZ AEROSPACE AIRBUS in Hamburg are presented. The investigations described in this paper have been performed within the context of technology studies, which are partially sponsored by the German Ministry of Defence.

IMPACT OF NEW INFORMATION TECHNOLOGY AND MICRO-TECHNIQUES ON AVIONICS FUNCTIONS AND STRUCTURES
Loise, Dominique, Sextant Avionique, France; Lacroix, Jean-Paul, Thomson-CSF, France; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 6p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The avionics functions of the 70s and 80s had a growth rate of their embedded processing resources consistent with the progress pace of the semiconductors technology. The avionics functions designed in the early 90's were impacted by information technology, LCC and availability requirements; they are enlightened by the shift from federated to integrated avionics architectures. The micro-techniques, which allow to combine analog sensing and/or actuating with local processing and communication resources, combined to the new trends of information technology in networks (client/server architectures), and the steady increase of semi-conductors technology, may initiate the move of the integrated avionics functions to the distributed micro-systems. These micro-techniques and their application fields are briefly described and their impacts on the architecture and functions are estimated. Some results come from advanced development of the Radar of the next generation, based on Active Array Antenna.

Preliminary conclusions are that commercial technology (COTS, Software tools, digital processing, communication protocols) will be usable; an aggregated increase of the communication requirements has to be expected from the distribution of the sensors all over the platform but placing the boundaries at the wrong place while distributing the system may actually worsen the communication issues, as some management and fusion/consolidation processing resources will have to remain centralized, notwithstanding potential exchanges between the distributed elements. These communication constraints, together with the cooling and power supply distribution issues, remain challenges that the avionics community would have to solve by itself.

MODERN FIGHTER MISSION AVIONICS: THE JOINT STRIKE FIGHTER AVIONICS ARCHITECTURE

Lachenmaier, Ralph, Naval Air Warfare Center, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 8p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The Joint Strike Fighter (JSF) program is potentially the largest new military aircraft program in the world today. A preliminary avionics architecture has been defined and published. Several efforts are underway to prototype and demonstrate various aspects of that architecture. The architecture will be refined and updated between now and the beginning of Engineering and Manufacturing Development (EMD) expected to begin in 2001. This paper describes the avionics architecture in its current state, discusses the motivation behind the various areas of the architecture, presents the issues involved, and discusses the results of some of the demonstration efforts. The JSF program is based on the four pillars: affordability, lethality, survivability, and supportability. First and foremost among the pillars is affordability. In order to field a lethal, supportable, survivable aircraft, affordability tradeoffs will be conducted by the prime contractors. Historically, 30-40 percent of weapons system life cycle costs have been attributed to avionics, hence reduction in avionics systems costs are essential in satisfying JSF pillar requirements. An F-22 technology point-of-departure has been used to baseline the avionics architecture planning. The JSF is leveraging that significant technology investment, conducting maturation of new contributing technologies, and implementing, where appropriate, COTS components, standards, and processes to enhance affordability of the next generation strike fighter. AGM-130 IMPROVED MODULAR INFRARED SENSOR (IMIRS) FLIGHT TEST

Corej, Thomas A., Flight Test Squadron (40th), USA; Kosan, Keith J., Flight Test Squadron (40th), USA; Advances in Flight Testing; Dec. 1997; 8p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The AGM-130/Improved Modular Infrared Sensor (IMIRS) weapon system is operationally compatible with the F-15E and F-111F launch platforms. The addition of a rocket motor to the GBU-15, making it an AGM-130, increases the standoff range of the AGM-130. The IMIRS seeker is an InfraRed (IR) seeker for the AGM-130, and the AGM-130/IMIRS system provides sufficient resolution for target detection in day or night. Using a two-ship scenario (one weapon-carrying aircraft and one controlling aircraft), the controlling aircraft can stand off at an extended classified range and successfully guide the weapon to impact. The aimpoint update feature of the IMIRS seeker allows for small changes to be made in the aimpoint allowing for precisely attacking a specific point on a target. When the Weapon

Systems Officer (WHO) locks-on to a target, he can slew to refine the Desired Mean Point of Impact (DMPI) and then lock-on to the new DMPI without breaking the lock on the original aimpoint.

A DATA ACQUISITION SYSTEM FOR THE RNLA F-16 REQUIREMENTS AND PROPOSAL

Koolstra, H. J., Royal Netherlands Air Force, Netherlands; Hollestelle, P. M. N., National Aerospace Lab., Netherlands; Klijn, J. M., National Aerospace Lab., Netherlands; *Advances in Flight Testing*; Dec. 1997; 6p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In 1983 the Royal Netherlands Air Force (RNLA F) requested the National Aerospace Laboratory NLR to design, procure and install a flight test data acquisition system to be used with the F-16 fighter aircraft. The design was heavily based on the systems, which were at that time nearing their completion for flight tests with Fokker aircraft. The system was delivered to the RNLA F in 1984 and has been continuously in use since that time. With the coming introduction of the Mid-Life Update programme of the F-16, it was foreseen that the current system would not be able to fulfill its tasks anymore. The RNLA F together with NLR draw up the requirements for a new data acquisition system. A proposal for the new system was made by NLR, again based on recent developments of flight test instrumentation for Fokker aircraft, but also with future developments in the field of airborne flight test instrumentation in mind. In this paper the requirements for the new system will be given. The proposed system will be described by means of a general concept. Although the final implementation of this general concept is not decided upon yet, the benefits and drawbacks of a possible implementation, based on the Common Airborne Instrumentation System standards, are discussed. It is concluded that there is a preference for this implementation, provided the tight time schedule can be met.

TORNADO INTEGRATED AVIONICS RESEARCH AIRCRAFT (TIARA)

Brown, A. D., Defence Evaluation Research Agency, UK; Stocks, A. J., Defence Evaluation Research Agency, UK; Dec. 1997; 10p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The paper describes the role, major features and flight trials programme of the Tornado Integrated Avionics Research Aircraft (TIARA). This significantly modified F2A(T) Tornado, ZD902, is the flagship of the trials fleet currently operated by the Defence Evaluation and Research Agency (DERA), an Executive Agency of the UK Ministry of Defence. TIARA is a multi-sensor, multi-role trials facility intended to demonstrate a "total systems integration" concept. It not only directly supports military customer programmes but also has sufficient capacity for collaborative programmes with other research organisations. Following a major conversion programme, ZD902 is now currently being used for the evaluation of IR sensors and helmet mounted displays. The future installation of the Blue Vixen AI radar will complete TIARA as a research facility and allow trials on sensor data fusion to begin.

This paper addresses the enabling technologies of the sensor suite for the next generation Unmanned Tactical Aircraft (UTA). An assessment is made of target sensors, communication sensors, and navigation sensors that are used in the UTA intelligence, surveillance, reconnaissance, communication, and target designation missions.

Emphasis is given to the classes of UTAs that operate at stand-off altitudes and ranges outside the effectiveness envelope of typical threat air defenses and jammers. Primary environmental factors that are addressed in the paper are world-wide cloud cover and rain rate. The effects of cloud cover and rain rate on sensor performance are evaluated for synthetic aperture radar (SAR), passive millimeter wave (mmW), and electro-optical (EO) sensors. The synergy of radar frequency (RF) sensors to improve the sensor suite performance in cloud cover and rain rate is addressed. The paper also addresses the enabling technologies that are required for real time, low false alarm rate (FAR), automatic target recognition (ATR) and precision targeting. A target sensor suite is postulated that is based on multi-spectral, multi-dimension discriminants of the target. An X-band or Ku-band SAR is considered to be the best overall target sensor for UTA applications. A priority ranking of other target sensors is ultra wide band (UWB) low frequency SAR, forward looking infrared (FLIR), laser infrared detection and ranging (LIDAR), visible, and passive mmW. The Year 2007 sensor suite would cover the multi-spectral range of VHF frequency to visible wavelength and the multi-dimensional parameters of contrast, two-dimensional shape, three-dimensional shape, temporal, and polarization signatures of the target.

These technologies; High speed processing, flat panel high resolution displays, voice activation, optical processing/networking, and helmet mounted displays; are mainstream enabling technologies for today's aircraft and/or aircraft now in development. It is not expected that the performance of subsystems based on them will be of adequate performance to cope with increased information availability, 24-hour availability and higher performance sensors. Specifically: High speed processing improvements, deriving from commercial components, will need to be available for increased data processing. Flat panel (color) high resolution displays in large sizes, eg. 30" x 12" will need to be adapted from, e.g. low cost field emission displays (FEDs) developed for commercial reasons in different aspect ratios, to provide an effective means for pilot situation awareness. Voice activation will allow the pilot to operate on a broader front with displays and controls, in high workload or high-g environments, and the military requirements will not be totally covered by commercial developments, e.g. in voice environment robustness. Optical processing/networking is an enabling technology for integrated modular avionics. Helmet mounted displays technology is still deficient in performance, head weight, integration with designation and head down displays.

FAULT TOLERANT HIGHLY INTEGRATED AVIONICS ARCHITECTURES

Timmers, H., Advisory Group for Aerospace Research and Development, France; Ott, L., Advisory Group for Aerospace Research and Development, France; *Aerospace 2020*; Sep. 1997; Volume 3, 73-74; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

Avionics is approaching 40% of the weight and cost of the aircraft. In order to reduce weight, cost and maintenance actions and provide affordably increased functionality, a highly integrated commercial-off-the-shelf (COTS) based avionics architecture must be developed. This architecture will be characterized by its modularity, resource sharing, fault tolerance attributes and wide use of commercial components. The overall dependability and fault tolerance of the next generation of highly integrated, COTS based avionics systems will be a critical factor in the effectiveness of those systems in future combat

scenarios. Thus the challenge is to demonstrate and validate that this high integration and the military real-time, fault tolerant and security requirements can be met with CTS/open system components.

RECOMMENDED PRACTICES FOR THE ASSESSMENT OF THE EFFECTS OF ATMOSPHERIC WATER INGESTION ON THE PERFORMANCE AND OPERABILITY OF GAS TURBINE ENGINES RECOMMANDATIONS CONCERNANT LES METHODES A UTILISER POUR LE TRAITEMENT DE L'HUMIDITE DANS LES TURBINES A GAZ

Sep 1, 1995; 364p; In English
Report No.(s): AGARD-AR-332; NIPS-95-06172; ISBN 92-836-1022-9; Avail: CASI; A16, Hardcopy; A03, Microfiche

The ingestion of water from the atmosphere into the inlet of a gas turbine can significantly influence the performance and operability of the engine. The objective of this report is to identify preferred practices to measure the effect of water ingestion on engine performance and operability. Atmospheric water is considered in all its forms; gaseous humidity, condensation droplets, rain, snow, and hail. The Introduction to Chapter 1 summarizes the purpose and background to the report and identifies the intended audience. Chapter 2 provides a quantitative assessment of the hazardous weather threat due to water for all types of aircraft using data collected from international sources. Chapters 3, 4, and 5 examine analytical and experimental techniques currently in use to measure and to predict the effects of the different forms of ingested water on engine performance and operability. Chapter 6 summarizes current acceptance and certification specifications used by different national agencies in assessing the effects of ingested water. In Chapter 7 a review is made of current instrumentation used to assess and quantify the presence of vapor, liquid droplets, and particles (frozen droplets) in the flow. Chapter 8 describes briefly current methods for testing gas turbine engines under typical weather threat conditions. The final chapter of the report summarizes the collected information on the effects of water ingestion from the preceding chapters and presents a set of conclusions and recommendations for future research.

Aircraft engine components experience severe operating conditions, often involving complex combinations of cyclic mechanical stress, cyclic temperature and varying environmental conditions. At the 81st meeting of the AGARD Structures and Materials Panel, the SMP held a Specialists' Meeting on Thermal Mechanical Fatigue of Aircraft Engine Materials to review the state-of-the-art experience in experimental methods as well as approaches to analytical modelling of damage accumulation and growth in metallic gas turbine engine materials under TMF conditions.

THERMOMECHANICAL FATIGUE IN GAS TURBINE ENGINES: THE REASONS OF A CONCERN

Lasalmonie, A., Societe Nationale d'Etude et de Construction de Moteurs d'Aviation, France; Pellerin, F., Turbomeca S.A. - Brevets Szydlowski, France; Fournier, D., Turbomeca S.A. - Brevets Szydlowski, France; Thermal Mechanical Fatigue of Aircraft Engine Materials; Mar. 1996; 6p; In English; See also 19960021124; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The improvement of the performance of gas turbine engines for military aircrafts or helicopters has been the result of a continuous evolution in the materials properties and the technology of the components. The result of this evolution is that the alloys experience complicated stress and temperature cycles; the life prediction based on isothermal characterization is no longer satisfactory. Classic isothermal tests do not discriminate enough for behavior validation and are sometimes unrealistic to describe damage mechanisms. In the case of the helicopter engines, technological evolutions contributed also to more severe temperature gradients. This paper presents in more detail the thermomechanical fatigue (TMF) concerns on the components which are submitted to the highest temperatures.

Standard design and analysis methods for determining fatigue life involve using fatigue data generated under isothermal conditions. The large temperature variations in the turbine section of gas turbine engines promote an interest in the effect of temperature cycling on fatigue life. Consequently, thermomechanical fatigue (TMF) tests have been conducted on a variety of materials to determine the effects of temperature cycling on fatigue crack initiation and growth. This paper reviews enhanced test methods, the results of such tests, life prediction methods, and makes recommendations for future work.

THERMAL MECHANICAL FATIGUE AND ITS EFFECT ON COMBUSTOR DESIGN

Sikorski, R. L., Wright Lab., USA; Thermal Mechanical Fatigue of Aircraft Engine Materials; Mar. 1996; 4p; In English; See also 19960021124; Copyright Waived; Avail: CASI; A01, Hardcopy; A03, Microfiche

In the past, a typical combustor design consisted of single-wall 360 degree rings with film cooling introduced periodically along the length of the combustor wall. This type of construction coupled with dilution and cooling hole discontinuities, created high local thermal stresses. The pressure levels also affected the radiation such that as pressure increased, thermal gradients and thus thermal stresses increased. Mechanical loads and stresses were directly proportional to the pressure loading in the combustor. The combination of these thermal and mechanical stresses caused premature failures in the combustor liners. Evidence indicates that dividing components into segments reduces mechanical load and thermal variations significantly. Combustor liner segments are supported by a load bearing structure such that pressure levels have a small effect on the segmented liner. These segments can also grow both axially and circumferentially, thus reducing thermal gradients in the liner. The resulting reduction in stress lowers the possibility of a catastrophic

failure in the component. The purpose of this paper is to trace the history of segment combustors, examining their role in today's technology, and to explore development for the future.

DAMAGE MECHANISM ASSESSMENT ON TURBINE BLADES SUPERALLOYS THROUGH TMF TESTS

Lautridou, J. C., Societe Nationale d'Etude et de Construction de Moteurs d'Aviation, France; Guedou, J. Y., Societe Nationale d'Etude et de Construction de Moteurs d'Aviation, France; Delautre, J., Societe Nationale d'Etude et de Construction de Moteurs d'Aviation, France; Thermal Mechanical Fatigue of Aircraft Engine Materials; Mar. 1996; 6p; In English; See also 19960021124; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The greatest advance in metal temperature and stress capability for turbine blades in the last 30 years has been the result of the development of directionally solidified single crystal superalloys. Two groups of alloys, called first and second generation, have been developed. The second generation alloys were essentially developed to improve the creep resistance and the long time phase stability in order to allow increased operating temperatures. Creep resistance is not the only property to be considered for life prediction. In complex shaped highly cooled turbine blades, stresses of thermomechanical origin may become at least as important as the centrifugal stress causing the creep of the material during the stabilized regime of the engine cycle. Those thermomechanical stresses are generated in particular during aircraft take off and landing operations. A limited amount of work has been done to compare the performance of the two generations of single crystal alloys regarding thermomechanical fatigue resistance. The aim of the present study was to compare the mechanical properties of four single crystal superalloys belonging to the first (AM1, AM3) and second generation (MC2, CMSX4). In order to get a complete comparison, creep rupture, and thermal mechanical fatigue (TMF) tests were carried out.

There are presented the main lines of the conducted in CIAM investigations of thermomechanical fatigue of aircraft engine parts materials. Based on a generalization of the results of extensive experimental investigations, it is suggested the strength criterion for non-isothermal cyclic loading with creep effect in every cycle involving two limiting characteristics: value of the limiting material deformation, determined in the conditions of single-cycle reverse loading at temperature changing by the $T(\min)$ approaching $T(\max)$ approaching $T(\min)$ regime; and value of limiting creep strain determined in the cyclic creep conditions. The analytical methods for determining a stress-strain state and the approaches for estimating a life in case of thermomechanical loading of turbine SC-alloy blades and coated blades are worked out.

The paper discusses the major parameters influencing the design of aero engine high pressure turbine blades and their contribution to the thermomechanical fatigue (TMF) behavior of these blades. Procedures for calculating transient temperatures and the role of such temperatures in determining thermomechanical stresses are considered. In turn, having established the major parameters influencing the TMF behavior of the blade, both stress and strain based life prediction models are considered. In-phase and out-of phase TMF test results of both plane and coated specimens are presented and the implications for lifting models are discussed. Finally, the form of future TMF models are briefly considered.

The Conference Proceedings contains 42 papers presented at the Propulsion and Energetics Panel 85th Symposium on Loss Mechanisms and Unsteady Flows in Turbomachines which was held from 8-12 May 1995, in Derby, UK. Sessions: Cascade Steady Flow Mechanisms and Losses (9 papers); Steady Flow Clearance and Injection Flow Mechanisms and Losses (6); Steady Secondary Flows and Shock Boundary Layer Interaction (3); Blade Section-Wake Boundary layer Interaction (6); Management of Unsteady Flows (10); Blade Interactions (8). The Symposium contributes to improving the efficiency and operation of turbomachinery also in off-design conditions by application of experimental and computational fluid dynamics methods. Multi-stage methods and positive loss management in the design stage have been identified as next steps. This will yield optimized engines of high efficiency for expanded flight envelopes including active control of the plane movement at high reliability levels.

ENDWALL BOUNDARY LAYER SEPARATIONS AND LOSS MECHANISMS IN TWO COMPRESSOR CASCADES OF DIFFERENT STAGGER ANGLE

Stark, U., Technische Univ., Germany; Bross, S., KSBAG, Germany; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 16p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

The paper describes experimental and theoretical investigations on the effect of stagger angle on the endwall flow in two compressor cascades, one with a low stagger angle ($\Gamma = 30$ degrees) and one with a high stagger angle ($\Gamma = 50$ degrees). The results of flow visualization tests, wake measurements and inviscid secondary flow calculations are shown for both cascades. The more important differences between the two sets of results are discussed with particular attention to 3D endwall boundary layer separations and loss mechanisms.

Flow patterns and losses prediction in a controlled diffusion airfoil cascade of an industrial axial compressor are demonstrated by means of a two-dimensional, explicit, time-marching fractional-step solver. The fractional-step algorithm presents certain advantages which are mainly related to its simplicity and the fact that greater time-steps are allowed, in comparison to other explicit solvers. In the present analysis, turbulence is modeled through both a low Reynolds k-E model and the algebraic Baldwin-Lomax one. The former is combined with an efficient artificial viscosity scheme, leading thus to a smooth E-field close to the solid walls. From a numerical point of view, the Baldwin-Lomax model cooperates perfectly with the basic numerical kernel. The k-E model, when used in conjunction to an explicit solver, is prone to instabilities and a particular semi-implicit treatment of the source terms is required. On the basis of the examined cases, differences in the predictive capabilities of the two turbulence models are presented and discussed.

A computational study is presented of the flow around a controlled-diffusion compressor-cascade blade at design as well as off-design conditions. In this flow, features associated with by-pass transition close to the leading edge - probably including laminar leading-edge separation contribute significantly to the evolution of the boundary layer on the blade surface. This has motivated the additional investigation of transition in a number of flows which are highly pertinent to the principal blade flow: two flat-plate boundary layers, a flow over a curved blade-like bump in a channel, and a flow past a rounded leading edge involving laminar separation and transitional reattachment. It is demonstrated that conventional eddy-viscosity models, based on the linear Boussinesq stress-strain relations, are able to capture by-pass transition in simple shear, but are unable to resolve transitional features in complex strain, especially those associated with leading edge separation, unless a mechanism is introduced to suppress excessive normal-strain-induced production of turbulence energy. The non-linear model is shown to return a considerably improved representation of the blade flow, resolving the leading-edge processes and returning a much improved variation of the loss as a function of the inlet angle of incidence.

The test results of a boundary layer developing on the suction side of the highly loaded turbine vane are presented. The tests of the boundary layer development were performed with hot film transducers deposited on a polyimide foil and glued to the profile wall. Special

attention was paid to a formation of a separation region. Total pressure losses with regard to the boundary layer condition on the suction side of the profile were determined.

This paper presents the results of a computational study on the effect of axial spacing between the vane and blade rows of a transonic turbine stage. The study was performed on the mid-span section of a high-pressure turbine stage using a quasi-3D, unsteady Navier-Stokes solver that provides a fully interactive vane-blade unsteady flow solution. Three different cases were considered, corresponding to axial spacings of 20%, 40%, and 60% of the vane axial chord. The calculated vane and blade pressure distributions for the 40 percent case were found to compare favorably with experimental measurements acquired in a short-duration shock tunnel. In addition, the analysis shows a marked increase in the amplitude of the unsteady pressure fluctuations on the vane and blade surfaces as the spacing decreases. Time-averaged stage adiabatic efficiency predictions for each case are presented to show the effect of spacing on aerodynamic performance.

A REVIEW OF THE RESEARCH ON UNSTEADY TURBINE BLADE WAKE CHARACTERISTICS

Cicatelli, G., Von Karman Inst. for Fluid Dynamics, Belgium; Sieverding, C. H., Von Karman Inst. for Fluid Dynamics, Belgium; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

The research on unsteady wake flows behind turbine blades is the orphan of turbomachinery research. The statement that blade wake flows are characterized by the presence of so called von Karman vortex streets, is a common-place, but yet, only very few researchers concluded that this phenomenon deserved their attention. The paper attempts to summarize the available bits and pieces and provides the reader with the state of art of our present knowledge in this domain. In many circumstances, the authors have to rely on research results on flows behind cylinder. Schlieren, interferometry and smoke visualizations are used to illustrate the existence of vortex street in a wide variety of cascade and flow conditions. The difference in the Strouhal number describing the vortex shedding frequency behind turbine blades and cylinders is explained and the effect of the vortical motion on the base pressure is discussed. A description of the vortex generation mechanism and the wake structure, developed for flows over cylinders, proves useful in the interpretation of the instantaneous stream lines in time varying turbine blade wakes containing large coherent structures.

SECONDARY FLOWS IN A TURBINE CASCADE AT OFF-DESIGN CONDITIONS

Bassi, F., Ancona Univ., Italy; Savini, M., Bergamo Univ., Italy; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 10p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A02, Hardcopy; A06, Microfiche

In this work a finite volume full 3-D Navier-Stokes solver equipped with the two equation k-w turbulence model is described. The code is applied to the analysis of the secondary flows occurring

in a low aspect ratio turbine cascade both at design and at highly off-design incidence angle. Numerical results and experimental data concerning loss, flow angle, and turbulent kinetic energy distributions are compared and discussed. Aim of the work is to investigate the capability of the physical models, namely of the turbulence model, to simulate the marked three-dimensional flow features that characterize the secondary flows at off-design conditions

TURBULENCE AND TRANSITION IN SECONDARY FLOWS IN A TURBINE CASCADE

Moore, H., Durham Univ., UK; Gregory-Smith, D. G., Durham Univ., UK; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 12p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

The accurate prediction of flows in turbomachinery blade rows requires realistic modelling of turbulence and transition, particularly for loss estimation. The complex secondary flow within a large scale cascade of turbine rotor blades has been measured in detail. In particular hot wire measurements have been made close to the end walls in order to characterize the three-dimensional boundary layers. Although at inlet on the end-wall there is a well developed turbulent boundary layer, this is rolled up into a loss core by the secondary velocities and a new highly skewed boundary layer is formed which exhibits significant laminar characteristics. The physical insights gained by this work have implications for the development of turbulence and transition modelling as well as providing test data for the verification of CFD codes.

Three-dimensional model of vortex flow in a passage is based on Clebsch's Transformation. The associated computer codes consist of the following modules: finite elements mesh automatic generation, finite elements optimum renumeration, calculation of flow, processing of results, analysis of losses. Losses analysis uses typical elements losses models: friction, turn, expansion losses and losses due to equalization throughout the flow. Two last components of losses are calculated by use of integrating throughout the streamlines of the passage element where the results of 3-D flow calculations are known. The model of mass flux averaged flow in turbine rows with end wall inclination, tangential lean or curvature of the blades has been developed. It is made due to the additional boundary condition along geometrical throats line of blade to blade passage. The boundary condition is radial distribution of meridional stream lines inclination which is based on the principle of flow mass flux maximum. Correlations between different flow models has been developed. Research of secondary flows control problem focuses on the effect of end wall fences, wall and blade ledges use for cross flows limitation. Combination of wall ledge and suction from ledge surface, blade through slots and holes used for gas transportation from pressure to suction blade surface in secondary flows area are also experimentally studied in axial turbines.

The tip clearance flow and loss production in a low speed linear compressor cascade with a moving endwall is investigated. The analysis is based on numerical computations with a 3D viscous code, at one tip clearance level. Comparisons with experimental data are given for the stationary wall case. The moving wall modifies significantly the secondary flow field near the wall, by generating the skewing of the inlet endwall boundary layer and dragging the tip leakage vortex towards the pressure side. It is found that the leakage flow near the wall is collateral over most of the chord. Close to the tip surface, however, the flow is highly skewed due to the vena contracta. With the moving wall, the leakage mass flow and pressure drop are noticeably increased.

Theoretical models for the investigation of the phenomena connected with the tip clearance are presented. A model was developed for the description of the flow through the gap, which recognizes the basic flow characteristics inside the gap. The mass flow rate as well as the pressure losses inside the gap are predicted with sufficient accuracy. A new method, based on the moment of momentum equation, is proposed for the calculation of the shed vorticity and the formation of the leakage vortex. A diffusion model for the vorticity distribution is used for the calculation of the pressure deficit field, so that the total pressure loss profile due to the presence of the leakage vortex, is derived. An algorithm is being set up for the implementation of the above models in a secondary flow calculation method. A complete theoretical procedure was developed, which calculates the circumferentially averaged flow quantities and their radial variation due to the tip clearance effects. The calculation takes place in successive planes, where a Poisson equation is solved, in order to provide the kinematic field. The self induced velocity is used for the positioning of the leakage vortex. The calculated pressure deficit due to the vortex presence is used, through an iterative procedure, in order to modify the pressure difference in the tip region. Calculation results are compared to experimental ones for axial flow machines. The agreement between theory and experiment is good.

TIP LEAKAGE LOSS DEVELOPMENT IN A LINEAR TURBINE CASCADE

Peters, David W., Turbine Specialties, Inc., USA; Moore, John, Virginia Polytechnic Inst. and State Univ., USA; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

Tip leakage losses were studied in a large-scale linear turbine cascade with a tip clearance gap equal to 2.1 percent of blade height. The cascade was located at the exit of a low speed wind tunnel; the blade exit Reynolds number based upon blade axial chord was 4.5×10^5 (exp 5). The flow was measured at a plane 0.96 axial chords downstream from the blade leading edge. Earlier studies performed at the tip gap exit and at a downstream plane 1.4 axial chords from the blade leading edge were utilized with the present study to understand loss development better. The effect of tip leakage and the corresponding loss production mechanisms involved as the flow mixes out were analyzed. The flow properties at the measurement plane were numerically integrated, to estimate the maximum potential loss of the

cascade, the flow was mixed-out through a momentum analysis. The loss at the measurement plane due to tip leakage was found to be equal to the sum of the total pressure loss within the tip gap and the dissipated tip gap secondary kinetic energy. As the flow proceeded downstream, losses were attributed to dissipation of secondary kinetic energy, trailing edge wake mixing, endwall losses, and primary flow mixing.

REDUCTION OF TIP CLEARANCE AND TIP CLEARANCE NOISE IN AXIAL-FLOW MACHINES

Kameier, Frank, BMW Rolls-Royce AeroEngines G.m.b.H., Germany; Neise, Wolfgang, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

An experimental study is described to investigate the negative effects of the tip clearance gap on the aerodynamic and acoustic performance of axial turbomachines. In addition to the increased broadband levels reported in the literature when the tip clearance is enlarged, significant level increases were observed within narrow frequency bands below the blade passing frequency. Measurements of the pressure and velocity fluctuations in the vicinity of the blade tips reveal that the tip clearance noise is associated with a rotating flow instability at the blade tip which in turn is only present under reversed flow conditions in the tip clearance gap. A turbulence generator inserted into tip clearance gap is found to be effective in eliminating the tip clearance noise and in improving the aerodynamic performance.

WAKE DEVELOPMENT DOWNSTREAM OF A TRANSONIC TURBINE INLET GUIDE VANE WITH TRAILING EDGE EJECTION

Kapteijn, Cornelis, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 8p; In English; See also 19960024804; Contract(s)/Grant(s): AER2-CT92-0044; Copyright Waived; Avail: CASI; A02, Hardcopy; A06, Microfiche

The temperature at the inlet of modern high pressure turbines requires an effective cooling of the nozzle guide vanes. This project investigates an annular cascade of internally cooled nozzle guide vanes with bleeding through a slot at the pressure side near the trailing edge. Purpose of the actual work is the determination of the downstream flow field undisturbed by the presence of the rotor with emphasis on the mixing process between main flow and coolant flow. During the second part of this project the investigation of a complete stage will take place, where the present results will enable the elucidation of the flow field deviations due to the rotor presence.

FLOW PREDICTIONS IN TRANSONIC TURBINES USING NONPERIODIC GRIDS

Hamed, A., Cincinnati Univ., USA; Yeuan, J. J., Cincinnati Univ., USA; Tabakoff, W., Cincinnati Univ., USA; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 10p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A02, Hardcopy; A06, Microfiche

Numerical results are presented for viscous flow through transonic turbine blades using different turbulence models and H-type grids. The numerical schemes for the solution of the compressible Navier Stokes equations are developed with an option of conservative zonal approach for interpolation across non-periodic boundaries to minimize numerical errors. This makes it possible to use nonperiodic type grids which are more orthogonal and less skewed for improved

accuracy in the prediction of turbine blade performance. The results obtained using traditional and nonperiodic H-type grids are compared with the experimental results for transonic turbine cascades and turbine stator vanes.

DEVELOPMENT OF AN OFF-DESIGN LOSS MODEL FOR TRANSONIC COMPRESSOR DESIGN

Bloch, Gregory S., Wright Lab., USA; Copenhaver, William W., Wright Lab., USA; O'Brien, Walter F., Virginia Polytechnic Inst. and State Univ., USA; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

A numerical investigation has been conducted to determine the changes in shock geometry that will occur with throttle setting for a modern transonic fan. The passage shock was found to be approximately normal near stall, with increasing obliqueness at higher mass flows. At peak efficiency, the shock system consists of an oblique passage shock followed by a normal shock, with the 2 shocks coalescing near the suction surface. As the back pressure is reduced further, the rotor becomes completely choked and the second shock moves downstream, becoming a separate, full-passage shock. The Mach number upstream of the second shock increases steadily as the shock moves downstream with decreasing back pressure. For all values of back pressure, the second passage shock is approximately normal to the predominant flow direction. Because the flow is supersonic downstream of the first passage shock, there are no changes in the first passage shock along this portion of the characteristic. A simple, but fundamentally based model has been developed which captures the qualitative trends of shock performance over the entire range of design-speed mass flows for a transonic fan. Model predictions are compared with measured data at multiple spanwise locations. The results of the comparison suggest that shock losses contribute a significant share of the total loss, but other mechanisms must also be considered.

SHOCK-WAVE TURBULENT BOUNDARY LAYER INTERACTION IN A HIGHLY LOADED TRANSONIC FAN BLADE CASCADE

Schreiber, Heinz-Adolf, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

Results of experimental investigations on strong shock-wave turbulent boundary layer interactions in a transonic compressor cascade are presented. The tests have been conducted in a linear cascade facility at inlet Mach numbers, ranging from 1.37 to 1.59, for freestream Reynolds numbers of about 2.7×10^6 (exp 6). The cascade tested is typical for a fan blade tip section with little flow turning, providing a static pressure ratio of more than 2.0. Main interest is concentrated on the blade suction surface, where the oblique extension of the bow shock of the neighboring blade forms a Mach reflection in combination with a boundary layer separation. Structure and loss mechanism of the shock system within the blade passage is discussed. Detailed measurements of the boundary layer within the interaction region and the rear part of the blade were performed. The results show that shock induced boundary layer separation on the tested blade can be controlled for inlet Mach numbers up to 1.42. At preshock Mach numbers of 1.32 to 1.44, there are only local boundary layer separations with reattachments. Complete boundary layer separation cannot be avoided beyond inlet Mach numbers of 1.45. However, the magnitude of the separation and thus the total pressure losses can be controlled by increasing the axial stream sheet contraction of the blade channel.

LOSS PREDICTION ON AXIAL FLOW CASCADES USING A NAVIER-STOKES SOLVER

Tinaztepe, H. Tugrul, Roketsan A.S. Ankara, Turkey; Akmandor, I. Sinan, Middle East Technical Univ., Turkey; Ucer, Ahmet S., Middle East Technical Univ., Turkey; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

In this paper, results of a 3D Navier-Stokes flow solver which uses a cell vertex finite volume method are given. The code uses Lax-Wendroff time integration method and Baldwin-Lomax turbulence model. Validation of the code are presented briefly in terms of modeling accuracy due to viscous effects. An attempt is made to predict shock boundary layer interaction on an airfoil. The paper also gives loss distributions. Effects like separation and secondary flow due to a high turning turbine cascade are discussed. Physical aspects of secondary flow and loss generation mechanisms are investigated in the predicted flow field.

Compressor and turbine blade boundary layers in axial-flow turbomachines are subject to periodically disturbed flow. This study modelled these conditions in a wind tunnel with circular cylinders traversing in front of a flat plate. Turbulent boundary layer velocity profiles on the flat plate were measured with a hot-wire anemometer. The ensemble-averaged turbulence intensity in the boundary layer was found to be significantly increased by the unsteady free stream flow, resulting in increases in the characteristic boundary layer thicknesses and the skin friction coefficient. The vortex structure within the unsteady cylinder wakes was found to explain the behavior of the velocity and phase angle profiles in the boundary layer.

This analysis has been performed from tests realized in a four stage low speed axial flow compressor (4000 rpm). First, two unsteady velocities components has been measured, using hot wire anemometry, directly upstream and downstream of the first stage stator in the (r,O) plane. Simultaneously, unsteady flow characteristics has been collected at four blade surfaces. Experimental techniques consisted first in pressure transducers fitted in the inner part of the profiles, then, in series of hot films (29), bounded, at two different radial positions, to the blade surfaces. These films were uniformly distributed orthogonally to the axial direction, from leading to trailing edges. Data have been processed in view to identify the multiple origins of excitation from the other parts of the machine and to describe the behavior of the boundary layer along the blade surfaces. Comparison of the experimental results with the ones given by a two-dimensional blade to blade computation method, taking into account the development of the boundary layer, has been performed.

Extensive pressure and thin-film measurements have been performed on a linear turbine cascade with variations of inlet angle, inlet Reynolds number, and inlet turbulence intensity at homogeneous and inhomogeneous inflow conditions. Especially the occurrence of laminar separation bubbles was investigated. With both measuring techniques their existence could be verified and the characteristic points of a bubble could be located. Incoming wakes similar to those in real turbomachines were simulated by a cascade of cylindrical bars which was positioned in front of the turbine cascade. Diameter and distance of the bars to the blades were chosen to produce nonuniformities in the cascade inlet plane similar to those in real engines. The wake impingement point could be varied by moving the cylindrical bars in circumferential direction parallel to the turbine cascade front. With this set-up the so called rotor-rotor or stator-stator interaction of a multistage turbine can be simulated. Measurements of direction, quantity and actuation of the velocity inside the boundary layer have been conducted with a Laser-2-Focus measuring technique. The analysis of the experiments results in a better understanding of the transitional phenomena on blade profiles and allows to improve empirical correlations for the calculation of transition in boundary layer.

A study of the effect of wake passing on the boundary layer of a modern low pressure (LP) turbine is presented. Typically, such blading operates at low Reynolds numbers. As a consequence, significant regions of laminar flow might be expected to occur together with transition via laminar separation bubbles. This paper examines the behavior of the surface boundary layers in environments typical of modern low pressure turbines. Results were obtained from arrays of surface mounted hot-film anemometers in the 3rd stage stator of a LP turbine. The results are considered in relation to more detailed experiments carried out in a steady flow high-speed linear turbine cascade and also with reference to tests carried out in a low-speed linear turbine cascade fitted with a mechanism that simulates the presence of upstream rotor wakes. It is found that, although there are some differ-

ences in details, the results from the turbine are consistent with the cascade observations. The suction surface boundary layer is little affected by wakes over the forward half of the surface and remains laminar. Downstream of peak suction, laminar separation occurs and the main effect of the wakes appears to be to promote transition in the separated region. Nevertheless, even in the presence of wakes, laminar flow persists for part of the time right up to the trailing edge. Over most of the Reynolds number range, the wake effects add to the loss, but at the lowest Reynolds numbers (Re less than 1×10^5) (exp 5), the wakes reduce the profile loss as compared to the steady flow situation, probably by assisting reattachment. The large element of laminar flow, even though there is considerable diffusion over the rear part of the suction surface, leads to low losses for this profile.

Fast response instrumentation has been used to measure the unsteady flow field in an axial flow turbine mounted in a transient test facility. The results show significant fluctuations in static pressure and heat transfer rate at mid-span on the rotor blade. The rotor is shown to have a limited influence on the heat transfer to the nozzle guide vane at midspan.

ROTATING STALL IN TURBOJET ENGINE COMPRESSORS

Borys, W. J., Royal Military Coll. of Canada, Canada; Moffatt, W. C., Royal Military Coll. of Canada, Canada; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 12p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

Losses in an axial compressor are generally ascribed to the effects of shock waves or viscosity, the latter including boundary layer growth, separation, wakes, and secondary flows. Rotating stall is a viscosity-related phenomenon whose effects are well understood, but whose origins and prediction have defied definitive analysis. Experimental approaches to understanding such stalls have for very practical reasons been performed primarily on laboratory scale compressors; there is little information in the open literature on installed units. This paper presents the results of several studies of rotating stall characteristics for a compressor in a turbojet engine, including determination of the conditions in which stall is found, the characteristics of the stall pattern, some details of the flows within the cells, and the effects of inlet distortions on the nature of the stall. Flow characteristics were found using hot film anemometer probes for all the tests. Also included is a brief description of an experimental evaluation of the effects of temperature changes within the compressor on the accuracy of constant temperature hot film anemometer measurements.

The results of experimental and numerical studies to examine the inception process of rotating stall and surge are presented. Unsteady pressure measurements have been carried out in a 3-stage high speed compressor to reveal characteristic features of instability onset. Tests have been conducted with clean intake as well as a circumferential inlet distortion. Analysis of the data shows that instability starts from small amplitude disturbances rotating in rotor direction, finally leading to either rotating stall or surge. A numerical model is used to calculate the instability onset in a compression system comprising of ducts, blade rows and volumes. The model is based on the unsteady two-dimensional Euler-equations in conservation law form. The influence of blade rows is simulated by source terms to account for pressure loss and energy input. Some results of computations are compared to the experimental results.

COMPARISONS BETWEEN UNSTEADY AERODYNAMIC EVENTS IN A GAS TURBINE GENERATOR AND AN IDENTICAL COMPRESSOR RIG

Owen, A. Karl, Army Research Lab., USA; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 18p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

Extensive testing done on a T55-L-712 turboshaft engine compressor in a compressor test rig is being followed by engine tests in progress as part of the Army Non-Recoverable Stall Program. Goals include a greater understanding of the gas turbine engine start cycle and compressor/engine operation in the regions 'beyond' the normal compressor stall line (rotating stall/surge). Rig steady state instrumentation consisted of 497 steady state pressure sensors and 153 temperature sensors. Engine instrumentation was placed in similar radial/axial locations and consists of 122 steady state pressure sensors and 65 temperature sensors. High response rig instrumentation consisted of 34 wall static pressure transducers. Rig and engine high response pressure transducers were located in the same axial/radial/circumferential locations in front of the first three stages. Additional engine high response instrumentation was placed in mach probes in front of the engine and on the compressor hub. This instrumentation allows for the generation of detailed stage characteristics, overall compressor mapping, and detailed analysis of dynamic compressor events.

SURGE AND STALL CHARACTERISTICS OF AXIAL-CENTRIFUGAL COMPRESSORS: THE ENHANCEMENT TO ENGINE STABILITY

Cousins, W. T., Garrett Turbine Engine Co., USA; Jones, M. G., Garrett Turbine Engine Co., USA; Belling, T. L., Garrett Turbine Engine Co., USA; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

The characteristics of axial-centrifugal compressors in gas turbine engines that provide an enhanced tolerance to engine stall and surge are presented. The incipient, post-stall, and recovery behavior of axial-centrifugal compressors is described. Unique high-response measurements showing the pressure/flow characteristics of post-stall behavior are presented and the measurement techniques are discussed. Comparison of compressor stall and surge, with and without a centrifugal stage, shows the benefit of using axial-centrifugal technology in gas turbine engines. A discussion is presented on the importance and the technique of detecting the compressor stage that has the potential to initiate instability under highly-loaded conditions. Data are presented from both compressor rigs and engines. An explanation of how to distinguish the stalling stage prior to surge in a compressor is included. The effect of interstage bleed on the axial-

centrifugal stage match in the engine environment is shown, along with the changes in surge initiation due to speed mismatch that can occur at high altitude conditions.

INITIATION AND PROPAGATION OF FLOW INSTABILITIES IN MULTI-STAGE AXIAL COMPRESSORS

Riess, W., Technische Univ., Germany; Walbaum, M., Technische Univ., Germany; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 12p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

Axial Compressors for all the different applications are required to have an operating range as large as possible with high efficiency. The increase of aerodynamic stage loading renders, however, a distinct narrowing of the characteristic field. Broader and deeper knowledge of the mechanisms governing the initiation and propagation of flow instabilities near the stability limit of compressors would permit an optimized compressor design with full exploitation of the aerodynamic limits, which could result in a considerably increased operating range. In addition new methods for instability detection could be found, which would allow operation near the surge limit with the aid of on-line surge control. The mechanisms of initiation and propagation of flow instabilities are investigated in a six-stage axial compressor with guide vane adjustment. by systematic modification of the aerodynamic loading of the different stages the propagation of disturbances and the interactions between disturbed and not disturbed flow in a multi-stage environment can be studied. Radial traverses with a six-hole probe and peripherally distributed pressure sensors render information on instationary flow phenomena as local backflows or transition from two-cell stall to single-cell stall. The results give the possibility to check different models for flow instability and develop methods for instability detection.

EULER MODELING TECHNIQUES FOR THE INVESTIGATION OF UNSTEADY DYNAMIC COMPRESSION SYSTEM BEHAVIOR

Davis, M. W., Jr., Sverdrup Technology, Inc., USA; Hale, A. A., Sverdrup Technology, Inc., USA; Shahrokhi, K. A., Sverdrup Technology, Inc., USA; Garrard, G. D., Sverdrup Technology, Inc., USA; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 10p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A02, Hardcopy; A06, Microfiche

The development of advanced turbine engine simulations is a necessity for the analysis of turbine engine dynamic events such as compressor surge, rotating stall, and inlet distortion. Simulations can fill information gaps and extend the range of test results to areas not tested. In addition, once a simulation has been validated, the model can become a numerical experiment and the analysis engineer can conduct 'what-if' studies to determine possible solutions to performance or operability problems. Turbine engine simulations can range from the one-dimensional cycle codes to the most complex computational fluid dynamics formulations. For dynamic events, the full Navier-Stokes solution is not feasible. However, computerized fluid dynamics (CFD) solutions using the Euler equations have achieved a good measure of success. This paper discusses both one-dimensional and three-dimensional Euler solution techniques that have been developed at the Arnold Engineering Development Center (AEDC) and applied to dynamic simulations for gas turbine engine compressors and the extension of the one-dimensional technique to the full turbine engine.

The purpose of this paper is to present a methodology for the prediction of unsteady flow resulting from rotor/stator interaction in multistage axial compressors. The methodology consists of a time-averaged multistage flow computation, which is used to initialize unsteady flow computations, dealing with a single stage and using chorochronic periodicity. Currently, time-marching Euler solvers are used for the time-averaged multistage computation, and for rotor/stator interaction computations, which can be coupled to an assumed-modes mechanical model. The development of a 3-D time-linearized Euler solver is also described. Typical results are presented and the methodology is validated through comparison with available data, both theoretical (analytical) and experimental. The updating of the methodology to Navier Stokes solvers is discussed in detail, and some preliminary results are presented. The urgent need for reliable and detailed unsteady aeromechanical experimental data is stressed as a major pacing-item in methodology development.

L., Societe Nationale d'Etude et de Construction de Moteurs d'Aviation, France; Burgaud, F., Societe Nationale d'Etude et de Construction de Moteurs d'Aviation, France; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 12p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

A numerical analysis of the unsteady flow field in a single stage axial transonic compressor is presented, with the aim of exhibiting typical unsteady phenomena resulting from the rotor-stator interactions. Firstly, a 3D Euler solver is used to investigate the unsteady effects generated by the inlet guide vane-rotor-stator relative motion, for several operating points of the compressor. Various features of the unsteady compressor flow field are examined: the non-uniformity of the flow in the stator, the influence of the operating point, and the location of the unsteadiness on each blade surface. A quasi-3D Navier-Stokes analysis of the inlet guide vane-rotor interaction is then conducted and shows the large influence of moving oblique shocks on the inlet guide vane instantaneous outlet angles and velocities.

UNSTEADY FLOW AND LOSS PRODUCTION IN CENTRIFUGAL AND AXIAL COMPRESSOR STAGES

Dawes, W. N., Cambridge Univ., UK; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 38p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

The aim of this paper is to help advance our understanding of the complex, three-dimensional, unsteady flows associated with the inter-blade row interactions in compressor stages. To achieve this, time-resolved, 3D, unsteady Navier-Stokes simulations were performed for two contrasting stages: a splintered centrifugal compressor with a

vaned diffuser; and a transonic axial flow compressor. The interest in the first stage is the interaction with the diffuser blades of the jet-wake flow emerging from the wheel. In the second stage the focus is on the interaction of the rotor over-tip leakage vortex with the downstream stator row. The predicted flowfields were interrogated from the perspective of loss production to try and determine any contribution of the unsteady flow to the loss levels and, hence, to the time-average performances of the stages. Specifically, the time-averaged entropy production rate was compared with the entropy production rate of the time-averaged flow. Thereby, any contribution to loss production directly associated with unsteadiness could be identified.

NUMERICAL INVESTIGATION OF INVISCID AND VISCOUS INTERACTION IN A TRANSONIC COMPRESSOR

Eulitz, Frank, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Engel, Karl, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Pokorny, Stefan, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

The paper presents inviscid and viscous results of unsteady flow calculations for a stator-rotor configuration of a transonic compressor. The calculations were run on a massively parallel hardware architecture. A second-order upwind total-variation diminishing scheme is employed in combination with a second order Runge-Kutta time integration method. The in- and outflow boundaries are treated with non-reflecting boundary techniques. The validity of the numerical method for time accurate calculations is thoroughly assessed by comparison to linear theory and experiments. In the analysis part of the paper, emphasis is on the stage interaction physics. A Fourier analysis of the stator blade pressure reveals fluctuations with a maximum amplitude close to 10 percent of the time-average. In the viscous case, the interaction of the observed propagating pressure waves with the boundary layer induces unsteady flow separation. Turbulence is accounted for by using either the Baldwin-Lomax or Spalart-Allmaras model. The influence of the turbulence model on the viscous solution is taken into account.

STATOR-ROTOR-STATOR INTERACTION IN AN AXIAL FLOW TURBINE AND ITS INFLUENCE ON LOSS MECHANISMS

Walraevens, R. E., Technische Univ., Germany; Gallus, H. E., Technische Univ., Germany; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

Detailed measurements have been carried out to investigate in particular the development of the rotor wakes and vortices, entering, passing and leaving the second stator. Pneumatic measurements in the axial gaps behind all blade rows provided information about the steady flow behavior. Hot-wire measurements with double- and triple wire probes have been performed behind rotor and second stator to acquire the time dependent three-dimensional velocity vector. Surface mounted hot film gages and highly sensitive subminiature pressure transducers were used to get information about the boundary layer behavior of the stator blades. This paper concentrates on the rotor flow and its time dependent influence on the flow behind the second stator. Results will be discussed mainly from figures showing time dependent secondary flow. Typical passage vortices dominate the rotor exit flow in the relative and absolute frame. It will be shown that the vortices leaving the rotor passage influence strongly the second stator exit flow.

This leads to highly three-dimensional unsteady effects. Even time averaged quantities show rotor flow phenomena in the exit flow of the second stator.

Detailed unsteady aerodynamic measurements have been taken in a single-stage transonic fan with a very high stage hub loading. 2D dynamic yawmeters were traversed at rotor and stator exit, while dynamic pressure sensors and heated thin-film gauges were fitted to the stator at mid-span. This paper concentrates largely on analysis and interpretation of the on stator measurements supplemented by consideration of some of the stator exit measurements and an inviscid-viscous prediction of the flow about the stator. These data show that at mid-span the rotor wakes augmented an incipient stator suction surface separation, causing a transient (larger) separation and reattachment. This gave rise to an acoustic disturbance which propagated upstream, where it interacted with subsequent rotor wakes. At these points of interaction, large amplitude static pressure fluctuations were induced. Wake convection was seen in both pressure and thin-film gauge data taken on the suction surface, although there was a complex relationship between both data sources. However, rotor wake convection was absent from the pressure surface pressure-field data despite evidence of 'negative-jet' effects convecting the rotor wake fluid toward the pressure surface of the stator.

M., Central Inst. of Aviation Motors, Russia; Loss Mechanisms and Unsteady Flows in Turbomachines; Jan. 1996; 14p; In English; See also 19960024804; Copyright Waived; Avail: CASI; A03, Hardcopy; A06, Microfiche

The investigation of a loss mechanism and flow pattern in a high load transonic single stage high pressure turbine is presented. The part of real vane row (vane sector) and midspan plane blade cascade were tested to obtain the flow structure and the level of losses for a wide range of outlet isentropic Mach-number from 0.7 to 1.4. During these tests flow visualization, total and static pressure and wake measurements were made. An inviscid and viscous computer codes and Bezier polynomials were used to the blade design by interactive technique. These experimental and calculated data were used for the stage design and analysis. The experimental stage was tested with changing of a tip clearance. The blade tip clearance values were measured by optical system. Comparison between measured and calculated performance of the experimental stage was carried out.

Shock waves shed from the trailing edges of current high pressure turbine blades for aircraft engines are believed to cause a decrease in the efficiency of downstream stages. A simulation of the

07 AIRCRAFT PROPULSION AND POWER

effects of unsteady shock waves is developed here, using a shock tube with multiple outlets to produce three shock waves. Time delays between the shocks are introduced using a duct length differential. The three shocks are passed upstream of a cascade of turbine blades traveling tangentially along the cascade leading edge. Shock periods of 0.055 msec and 0.200 msec are used. Shadowgraphs of the shock diffraction in the blade passages are presented. The shocks are also found to have a significant effect on unsteady blade static pressures and forces.

The Propulsion and Energetics Panel Symposium on Advanced Aero-Engine Concepts and Controls was held from 25-29 September 1995 in Seattle, Washington, USA. It dealt with propulsion, including thrust vectoring, for future combat aircraft, vertical landing aircraft and transport aircraft. Better fuel efficiency, longer range and higher operational flexibility will be gained from aero engines with advanced cycles which require improvements in fluid dynamics, materials and cooling. Five Sessions (37 papers including the keynote): Engine research and demonstration, requirements and programmes (3); Aircraft engine integration (5); Propulsion system and component technology (10); Engine control systems (13); Integrated flight and propulsion control (5). Dual use application of results is intended.

This paper discusses the purposes (background, goals, and applications) and the status of the Integrated High Performance Turbine Engine Technology (IHPTET) program through July 1995. IHPTET is a coordinated, three phase, government and industry sponsored propulsion program. It includes virtually all government and industry sponsored research and development (R&D) activities devoted to advancing technology for military turbine engines.

Requirements for a high performance weapons system that go beyond aeronautical programs already underway, among which are the Eurofighter 2000, the Rafale, and the F-22, are leading to constant study on aspects for improvements to the quality of the carrier aircraft such as: the air frame, armament system, engine system, and integration. In addition to the simple set of rough performance features, it will also be necessary to manage the ownership cost (life-cycle costs) of these new systems. Progress made by engine developers is traditionally measured by means of: the thrust to weight ratio of the propulsion system, the specific consumption (at full speed and at partial modes during supersonic or subsonic cruising) of the turbojet engine, discretion (radar electromagnetic signature and emissions radiating in the infrared range), acquisition and use cost of the equipment. A program to improve the characteristics mentioned above has already begun. It is the advanced military engine technology (AMET) program.

This paper examines how advanced engine technology can affect the design and performance of an air-to-air combat aircraft optimized for typical combat air patrol and intercept missions. The impact of cycle temperatures, component efficiencies, cooling effectiveness and engine thrust-weight ratio are studied independently to assess the relative benefits of each aspect of engine technology. Both fixed and variable cycles are considered, enabling the contributions of advanced technology and of cycle variability to be separated.

Future combat engines will operate at higher turbine temperatures and overall pressure ratios, which will enable high specific thrusts and good low power specific fuel consumption to be realized. The application of these technologies into aircraft needs to address the weapons platform requirements of agility, range, combat persistence. The influence of engine rating schemes and aircraft performance requirements are discussed with indications that higher specific thrust engines will be required for increase force projection.

THE STRATO 2C PROPULSION SYSTEM: A NEW COMPOUND ENGINE AND CONTROL CONCEPT FOR HIGH ALTITUDE FLYING

Toenskoetter, H., Industrienanlagen-Betriebsgesellschaft m.b.H., Germany; Scheithauer, D., Industrienanlagen-Betriebsgesellschaft m.b.H., Germany; Jun. 1996; 14p; In English; See also 19960054418; Copy-

right Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The propulsion system for the STRATO 2C high altitude long endurance (HALE) aircraft is an example of the development of a power plant that is tailored to a special unconventional usage and even takes advantage of the reliability and low cost of available components as well as the advanced technology of turbine engines. The disadvantages of a compromise in the optimization of the propulsion system did not jeopardize the overall design philosophy. The task of designing a low risk, low cost control system was achieved by: a conventional certified engine control system, and a new digital control system for matching the turbocharger stages under steady state and transient operating conditions for cooling flow control and for rotor speed and manifold pressure limitations.

The objective of this paper is to demonstrate the benefits and challenges of advanced propulsion system technologies on a vertical take-off and landing (VTOL) transport aircraft. The study concentrates on two types of propulsion concepts: mechanical and gas driven configurations. Both use turbofans for cruise and lift fans for vertical operations. A conceptual design analysis for the propulsion components is presented. Unique propulsion design characteristics associated with VTOL aircraft are discussed as well. These include sizing, hover, and operational constraints.

This paper discusses the design requirements and major challenges associated with powerplants for short take-off and vertical landing (STOVL) capable aircraft currently being studied under the Joint Advanced Strike Technology (JAST) program. Challenges specific to four different lift system concepts are described, namely: direct lift, shaft driven fan, gas driven fan, and lift plus lift cruise. Generic issues that must be resolved for any of these powerplants, namely: exhaust design, attitude control provision, reliability and affordability, are also discussed. All of the proposed concepts present significant challenges to the engine maker, particularly if the powerplant is to be used in a conventional take-off and landing (CTOL)/STOVL aircraft as proposed for the JAST program.

The costs of advanced high performance gas turbine engines for future military fighter aircraft applications are explored. The impact of increasing engine performance on the cost of the aircraft was examined and it was found to have a favorable impact on the cost of the weapon system. From an engine viewpoint, advanced component performance and improved cost effective manufacturing methods combine to significantly lower the cost of gas turbine engines on a per pound of thrust basis. Engine component costs were compared and

analyzed for a modern fielded engine and an advanced technology, high performance engine. Manufacturing costs and the implication to overall engine cost reduction for advanced technology engines were explored.

ADVANCED SMALL TURBOPROPULSION ENGINES

Rodgers, Colin, Sundstrand Turbomach, USA; Jun. 1996; 12p; In English; See also 19960054418; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Candidate advanced turbopropulsion engines to fulfill the requirements for the next generation military small aircraft, drones, and missiles are: turbojets, turbofans, turbofans, air turbo-ramjets, pulsejets, and combinations thereof. Prime requirements are to provide significant range increases with high flight Mach numbers and, in some applications, extended endurance above the tropopause, both of which are primarily dependent upon propulsion system specific fuel consumption trends. Other combinations of turbojets, rockets and ramjets are being studied for operation at even higher Mach numbers, but generally involve variable geometry inlets and exhausts difficult to incorporate on small propulsion vehicles. Preliminary design studies of a variety of advanced small turbopropulsion concepts was conducted recently by the author and associates, including: small stoichiometric air-turbo-ramjets, high pressure ratio intercooled turbo-prop, semi-constant volume turbojet, regenerative feedback turbine engine. This paper compiles the results of these studies and highlights the design features necessary to attain advanced levels of performance.

This paper describes a performance study of a compact turboshaft engine based on two concepts that can contribute to the performance gains of advanced future propulsion systems: the recuperative cycle and the variable geometry. Cycle optimization is done for a medium helicopter application, minimizing the fuel consumption and taking into account moderate levels of peak gas temperature to guarantee adequate life of the most critical engine hot components. The engine architecture (1000 kW class turboshaft with free turbine) is based on a minimum number of turbomachinery components to reduce the weight of the propulsion system and its global cost (initial and operative). The three gas generator components are: (1) a transonic, high performance, 8 to 1 pressure ratio single stage centrifugal compressor; (2) a very compact, reverse flow, annular flame tube, having a 1600 K combustor exit temperature; (3) a high-loaded, cooled axial flow turbine stage. The variable geometry free-power turbine is counter rotating with respect to the gas-generator rotor and the power output is available at the rear-end of the engine. A heat exchanger recuperator, placed behind the power turbine, contributes to a significant reduction of the engine specific fuel consumption. The components of the engine gas-generator section are based on the results of company research projects in the application of the most advanced computational fluid dynamics (CFD) techniques for the aero-thermal design of turbomachinery and combustors.

This paper describes several of the concepts evaluated during the last three decades, starting with the Air Force defined variable pumping compressor (VAPCOM) and concluding with a general description of the YF120 variable cycle engine (VCE) that flew in the YF-22 and YF-23 advanced tactical fighter (ATF) prototype aircraft. Section 1.3 describes the final evolution of the F120 type VCE and section 1.4 briefly addresses the current status of VCE development. These development activities lead to an affordable engine that combines the attributes of a high turbine turbojet, i.e. high dry specific thrust and low maximum power specific fuel consumption, with those of a turbofan, i.e., low partial power specific fuel consumption with low gas exhaust temperatures.

To predict the engine performance at subsonic and supersonic design and off-design flight conditions a thermodynamical calculation procedure has been developed that describes the engine performance with the help of generalized turbine and nozzle characteristics. To demonstrate the advantages of new engine concepts, including variable cycle and/or intercooler, on an aircraft with a payload of about 10,000 kg a realistic flight trajectory has been chosen, which involves every phase along the entire flight path: take-off, climb, supersonic acceleration, cruise, and descent. The results for the chosen flight routes, including fuel flow rates and NO₂ emissions, are compared to a zero-bypass engine, the Olympus 593 Mk610, producing comparable thrust.

With a single stage to orbit (SSTO) engine using aerobic propulsion, a considerable gain in the useful load fraction can be obtained only if one reaches at least Mach 14-15 in the aerobic mode. In order to reach this performance level, the use of a scramjet engine with hydrogen fuel is mandatory. This study five analytical results of the sensitivity of performance parameters of a scramjet engine called the Hyperjet Mk.3 (projecting part, external ramp with three segments, supersonic diffuser, insulator, combustion chamber, and internal and external ejection nozzles) that uses hydrogen slush as the stored fuel. Furthermore, it uses active cooling of the airframe walls and of the engine to reheat the fuel after injection. This study was conducted at Mach 15 with a dynamic pressure of 60 kPa and constant total angle of incidence equal to 11 degrees. The code used is an aerothermody-

namic code 1.5-D with viscous effects in which the air is considered as the mixture (with nine ingredients) of perfect gases that chemically react with one another.

This paper highlights the technological challenges associated with combined-cycle engines for hypersonic flight (Mach 0 to Mach 7). At first, different possible engine concepts are discussed. Selection criteria such as operating requirements and other boundary conditions are used to narrow down the number of concepts. Furthermore, the technological challenges associated with combined-cycle engines are presented with respect to the selected baseline engine.

The propulsion system for the lower stage of a two-stage-to-orbit transport system (TSTO) is presented with its main components: mixed compression air inlet, combustion chamber, and single expansion ramp nozzle (SERN). Using an implicit finite-volume Navier-Stokes code the flow fields in these components are studied. Comparisons between experimental data and computational fluid dynamics (CFD) calculations are presented for a two-dimensional high speed inlet, a high temperature reacting three-dimensional combustion chamber flow, and a two-dimensional nozzle/afterbody flow field. To determine the forces and moments acting on the propulsion system, comprehensive studies were performed from transonic to hypersonic flight Mach numbers. The results of these studies form the basis for an accurate description of performance and operating behavior of the propulsion system by performance analysis. At hypersonic speeds the effects of the propulsion system on flight-mechanical behavior is substantial, especially in the event of engine failures. Two failure scenarios were considered: flame out and inlet choking. For both cases, the forces acting on the propulsion system are shown.

A turbo-ramjet engine is investigated for the acceleration flight mission of the the lower stage of a two stage space transportation system. The method described in this paper allows for the optimization of the engine control parameters in parallel to the engine performance calculations. For a turbo-ramjet engine, the results of the optimization for an ascent flight mission was well as for the transition from turbo to

ram operation are presented. The results show a strong, highly nonlinear sensitivity of thrust and fuel flow to the flight conditions and engine control parameter settings.

APPLICATION OF A SYSTEM FOR THE MONITORING OF AERODYNAMIC LOAD AND STALL IN MULTI-STAGE AXIAL COMPRESSORS

Hoenen, H., Technische Hochschule, Germany; Gallus, H. E., Technische Hochschule, Germany; Advanced Aero-Engine Concepts and Controls; Jun. 1996; 10p; In English; See also 19960054418; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

As part of a complete health monitoring system, the observation of aerodynamic compressor load and the detection of stall in multi stage axial compressors is explained in detail. First, the definition of monitoring parameters and the choice of a suitable measuring technique is demonstrated. Based on the design of the system structure, the hardware and software solution is shown. Checking modules and a failure detection mode for all components makes up a large part of the software. With the help of suitable input and output interfaces the system can be adjusted for various applications and the monitoring results can be made visible. Furthermore, the experiences with this system as applied to three multi-stage compressors are reported. The behavior of the monitoring parameters shows a good agreement with the different operating conditions of the compressor as well as for design conditions and operation near the stability limit.

As the aerospace industry adjusts to post cold-war budgets, emphasis is shifting rapidly to demonstrating technologies of the future with modern-day fighters before committing them to production. Pratt and Whitney, together with NASA Dryden, US Air Force Wright Laboratories, and McDonnell-Douglas have developed such a system based on the F-15. This testbed aircraft has the capability to demonstrate a wide array of aerodynamic and propulsion integration technologies that will apply to future commercial and military aircraft design. This paper presents the ways and means of how Pratt and Whitney designed, manufactured, and flight tested affordable axisymmetric exhaust nozzles incorporating multi-directional thrust vectoring for the Advanced Control Technology for Integrated Vehicles (ACTIVE) program.

OPTIMIZATION OF ACTUATION AND COOLING SYSTEMS FOR ADVANCED CONVERGENT-DIVERGENT NOZZLES OF COMBAT AIRCRAFT

Sanchez-Tarifa, C., Sener Ingenieria y Sistemas S.A., Spain; Rodriguez-Fernandez, M., Sener Ingenieria y Sistemas S.A., Spain; Rebolo, R., Sener Ingenieria y Sistemas S.A., Spain; Corchero, G., Sener Ingenieria y Sistemas S.A., Spain; Rodriguez-Martin, M., Industria de Turbo Propulsores S.A., Spain; UlizarAlvarez, I., Industria de Turbo Propulsores S.A., Spain; Jun. 1996; 8p; In English; See also 19960054418; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The system or components of a convergent-divergent (CON-DI) nozzle that offer better perspectives for improvement and optimization are the actuation and cooling systems. Performance offers little margin for a direct improvement, and the utilization of advanced materials in many components of the nozzle present no specific problems as compared with those of other parts of the engine, with the exception of the petals, in which the introduction of ceramic materials has a direct influence on cooling and performance, and it is included in the cooling optimization. The problem of optimization of the actuation system was discussed earlier, mainly in connection with the utilization of a one versus two parameter actuation system. Since that time SENDER and ITP have carried out many studies and tests on actuation systems and on cooling optimization. They also have accumulated experience by means of theoretical and experimental studies on the utilization of ceramic petals. Some results and the main conclusion of these studies and tests are presented in this paper.

The search for better performance of present and future turbofan engines involves an increase in the number of variable geometries and thus of control loops. As we can not, or do not, want to disregard the interaction between loops any more, the future control systems will therefore be multivariable. The aim of the architecture of multivariable control presented here is to optimize a performance index during transients. This architecture consists of an inner loop which optimizes the performance index taking into account the limitations, an outer loop which brings the nominal steady-state offsets to zero, and a trajectory that takes into account the topping schedule limitation. This basic architecture can be improved by a fuzzy supervisor. Indeed, two control outputs are generated according to the description mentioned above. The first one optimizes the thrust and does not care very much about the low pressure stall (LPS) margin limitation. The second one optimizes again the thrust and strongly takes the LPS margin limitation into account. The fuzzy logic then provides for a compromise between these two control outputs according to the engine state. Simulation results showing the efficiency of the method are presented.

The appearance of full authority digital electronic control (FADEC)-type regulations for helicopter turbine engines in recent years has considerably enriched the engine control function. Helicopter usage has been made easier and the pilot's workload reduced, with the engine and power transmission train being automatically maintained within their limits. Maneuverability of the helicopter has been improved by rotor speed regulation performance features. The opportunity for strict management of engine emergency operating conditions, greatly superior to continuous maximum conditions, has led to considerable improvements in the performance parameters of two-engine helicopters in one engine inoperative (OEI) situations. Functions that will help in pilot training for this breakdown configuration are integrated into the control functions.

This paper describes dynamic simulations of transient performances applicable to modern military engines. This document is dedicated to the diverse tasks conducted regarding dynamic engine behavior control that are to be solved using an analytical process that relies on dynamic simulations of the engine and its systems. The main features of the engine transient model, its real-time version, and the identification tools that ensure evolution of the features are presented. Some applications are: the interpretation of tests (determination of in-situ compressor surge line position, analysis of engine response during flight testing, etc.); the design of control laws (effect of dynamics of a given element on the engine response, assessment of the response of the most critical engine).

This work deals with the application of neural techniques to control a turbofan engine exhaust nozzle area. The process exhibits strong non-linearities and thus it is difficult to control with classical methods. Neural networks are used with an approach inspired by indi-

rect adaptive control. The neural controller consists of two neural networks which communicate with each other. One achieves the identification task while the other controls the nozzle area. The simulation results of the process with a neural controller are given and compared with current results. The neural controller is better than the classical one and leads to a significant improvement in engine performance. Furthermore, the method can be used easily to control any non-linear dynamic system.

Preliminary results are presented on the development of an adaptive neural network based control algorithm to enhance aircraft engine performance. This work builds upon a previous NASA effort known as performance seeking control (PSC), an adaptive control algorithm that contains a model of the aircraft propulsion system which is updated on-line to match the operation of the aircraft's actual propulsion system. The neural network based adaptive control, like PSC, will contain a model of the propulsion system that will be used to calculate optimal control commands on-line. It is hoped that it will be able to provide some additional benefits above that provided by PSC. Since the PSC algorithm is computationally intensive, it is valid only at near steady-state flight conditions and has no way to adapt or learn on-line, these issues are being addressed in the development of the optimal neural controller. Specialized neural network processing hardware is being developed to run the software. The algorithm will be valid at steady-state and transient conditions, and will take advantage of the on-line learning capability of neural networks. Future plans call for the testing of the neural network software and hardware prototype against an aircraft engine simulation.

The goals of the Integrated High Performance Turbine Engine Technology (IHPTET) initiative demand that controls and accessories (C/A) weight, acquisition cost, and support cost be significantly reduced for modern gas turbine engines. Distributed control technology is one of the few approaches that has the potential to effect reductions in all three categories. Weight can be reduced by replacing the traditionally complex full authority digital electronic control (FADEC) and heavy harness assembly with light-weight distributed processing elements interconnected via a simple communication and power distributing bus. Simplification of FADEC interfaces makes off-engine mounting feasible, enabling an acquisition cost reduction that is greater than the cost increase incurred by adding electronics to engine sensors and actuators. Distributing intelligence throughout the engine will improve the control system's ability to isolate faults. The resulting reductions in time to troubleshoot and unnecessary component removals will decrease maintenance costs. Since high temperature electronics are the key to the viability of the distributed control concept, recent developments in this area are reviewed.

The use of photonics on aircraft gas turbine engines offers weight savings, electromagnetic interference (EMI) immunity, and performance benefits for engine control systems. For these reasons, fly-by-light technology is being developed for use in future aircraft control systems. Full authority digital electronic control (FADEC) systems that are compatible with fly-by-light aircraft and that use fiber optics on the engine for sensing and control are under development at United Technologies Corporation. Pratt and Whitney has made progress in transitioning fiber optics sensors, harnesses and opto-electronic FADEC (OEF) interfaces to engine demonstration programs. This paper discusses the benefits of photonic propulsion control systems, describes the components of an opto-electronic engine control system, provides results from on-engine testing, presents lessons learned and discusses areas that require additional development to achieve technology readiness for product transition.

This paper investigates an electric fuel control unit for small gas turbine engines, with valves operated by linear digital actuators. The unit is based on the modified metering section of a conventional hydro-mechanical fuel control unit. A mathematical model of the system is first developed and validated by experimentation. It is subsequently used for simulation and further study of the system dynamics. It was demonstrated that this new system features greater functional flexibility and faster transient response than the conventional system. The possibility for back-up, in case of failure of one valve also is discussed.

Active control technology (ACT), as applied to modern conventional take-off and landing (CTOL) aircraft has been extended to integrate the flight and propulsion control systems of a Harrier aircraft. This

extension allows the direct control of all the forces generated on the aircraft, but it is the control concepts and management options, that are under investigation. An experimental integrated flight and propulsion system (IFPC) has completed Phase 1 flight trials and has demonstrated consistent pilot workload reduction for the recovery task. Comparisons between different methods of controlling the aircraft, including a 1-inceptor option, are presented and the implications for the technology on the engine power off-take for hover control is discussed.

This paper discusses the accomplishments and benefits of the PROLIFIC, a tool set for the development and evaluation of an integrated flight and propulsion control (IFPC) system for flight critical applications. The material presented focuses on IFPC development tools for present and future military tactical aircraft. These tools are required to develop and thoroughly verify all propulsion system components prior to flight. Propulsion control systems become flight critical for aircraft configurations such as short take-off and vertical landing (STOVL) and reduced tail area aircraft with thrust vectoring engine nozzles. As aircraft flight control systems become more coupled with propulsion systems, so does the need for highly integrated control laws and associated development tools such as PROLIFIC.

This paper describes a baseline inlet system with respect to propulsion integration technologies. Previous operational inlet designs maximized total pressure recovery, minimized distortion at the engine face, and minimized overall frontal observables. Current budgetary realities have caused a shift in the technology development approach to maintaining current levels of inlet system aerodynamic performance at a reduced life cycle cost and/or increased aircraft utility. The current USAF inlet technology development goals for the year 2000 include: a decreased inlet weight by 50% from current base-

07 AIRCRAFT PROPULSION AND POWER

lines, a decreased inlet volume by 50% from current baselines, and maintain or increase current inlet performance levels. The baseline inlet system is the current state-of-the-art in inlet systems technology, a caret inlet aperture with a long, serpentine subsonic diffuser. This design provides for high aerodynamic performance and survivability throughout the tactical fighter envelope.

The design of intakes and afterbodies for hypersonic vehicles with RAM air breathing propulsion systems is described. The aerodynamic aspects of the integration of the forebody with the intake and the afterbody with the nozzle are outlined. The potentials and deficits of modern available tools are demonstrated and a strategy for the design of the propulsion system for a hypersonic vehicle is proposed.

The material to be presented in these two lectures begins with cycle considerations of the turbojet engine combined with a ramjet engine to provide thrust over the range of Mach 0 to 5. We will then examine in some detail the aerodynamic behavior that occurs in the inlet operating near the peak speed. Following that, we shall view a numerical simulation through a baseline scramjet engine, starting at the entrance to the inlet, proceeding into the combustor and through the nozzle. In the next segment, we examine a combined rocket and ramjet propulsion system. Analysis and test results will be examined with a view toward evaluation of the concept as a practical device. Two other inlets will then be reviewed: a Mach 12 inlet and a Mach 18 configuration. Finally, we close our lectures with a discussion of the Detonation Wave engine, and inspect the physical and chemical behavior obtained from numerical simulation. A few final remarks will be made regarding the application of CFD for hypersonic propulsion components.

A comparison of the performance of storable, liquid hydrocarbon fueled, scramjet-powered axisymmetric missile configurations using several types of fuel piloting/ fuel pre-preparation methods are presented along with an initial methodology to permit these comparisons to be made. The merits of each engine type are discussed, and a first attempt at defining an upper flight Mach number bound on these types of engines is presented.

Airbreathing sustained hypersonic flight could have operational advantages for military applications. By another way, airbreathing propulsion could have a potential interest for the future reusable launcher, in connection with rocket engines. High speed ramjets (scramjet and dual mode ramjet) are a key technology for these two kinds of military or space future applications. Airbreathing launcher using scramjet have been recently studied in France within the scope of PREPHA program. The chosen concept, which seems to be the most power full and robust, is a dual mode ramjet, associated with rocket engines completely separated. More generally, the use of scramjets for launchers is typically associated with hydrogen as a fuel, a maximum airbreathing Mach number of 12, and reusability. Less energetic fuels could also be used in dual fuel ramjets to take benefit of their higher density.

A Rocket Based Combined Cycle (RBCC) engine system is designed to combine the high thrust to weight ratio of a rocket along with the high specific impulse of a ramjet in a single, integrated propulsion system. This integrated, combined cycle propulsion system is designed to provide higher vehicle performance than that achievable with a separate rocket and ramjet. The RBCC engine system studied in the current program is the Aerojet strutjet engine concept, which is being developed jointly by a government-industry team as part of the Air Force HyTech program pre-PRDA activity. The strutjet is an ejector-ramjet engine in which small rocket chambers are embedded into the trailing edges of the inlet compression struts. The engine operates as an ejector-ramjet from takeoff to slightly above Mach 3. Above Mach 3 the engine operates as a ramjet and transitions to a scramjet at high Mach numbers. For space launch applications the rockets would be re-ignited at a Mach number or altitude beyond which air-breathing propulsion alone becomes impractical. The focus of the present study is to develop and demonstrate a strutjet flowpath using hydrocarbon fuel at up to Mach 7 conditions.

Within the last few years MTU has made a great development effort towards high-speed nozzle design, manufacturing, hot-gas testing and test analysis as part of the German Hypersonics Technology Programme. Within the framework of this programme two actively cooled nozzles were designed, fabricated and tested in 1993 and 1995, respectively. Whereas the first nozzle was cooled with cryogenic hydrogen, gaseous hydrogen was used for the latter. In this paper the associated nozzle design, fabrication and test effort will be described and highlighted. Focus will be placed on the experience gained by testing the actively cooled, fully variable nozzle structures.

Two test facilities for hydrogen combustion in supersonic air flow were developed in the context of studies on superathodyds [ramjet]. One is dedicated to basic studies of reactive supersonic mixture layers; the other one deals with the evaluation of concepts of injection and of combustion chamber. These facilities and the related instruments are described. Initial results demonstrate their capacity to produce supersonic combustion flows and to supply data on the inflammation time and on the elementary injectors.

OVERVIEW OF PROPULSION PERFORMANCE

Billig, Frederick S., Pyrodyne, Inc., USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 12p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Nearly forty years have passed since the concept of the supersonic combustion ramjet, scramjet, was first introduced. At that time, the exciting potential of airbreathing propulsion for both expendable missiles and highly efficient space launch systems were proposed.

Conceptual vehicle designs, engine flowpaths, including methods for injection and flame stabilization, and estimates of cycle performance were developed. Calculations were made for typical climb and cruise trajectories which showed distinct advantages of the scramjet over all-rocket powered systems. In the intervening years, prior to the initiation of the National Aero-Space Plane (NASP), a significant technology data base had been established which had substantiated the levels of performance that had been predicted by the pioneers. Nonetheless, no system utilizing the scramjet propulsion system had been developed. On every occasion, when a selection between a scramjet and an all-rocket system had been made, the all-rocket has prevailed. Paradoxically, the NASP, which was to be a single stage access to orbit vehicle, never was required to consider an all-rocket-powered alternative. Unfortunately, NASP failed to meet its stated objectives, in part due to unforeseen limitations of the propulsion cycle, and the program was cancelled. It is prudent to examine the underlying reasons for both the decision to cancel NASP and the reluctance to select scramjets for other applications.

BALANCING AFFORDABILITY AND PERFORMANCE IN AIRCRAFT ENGINES

Williams, J. C., General Electric Co., USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 6p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The historical measure of performance of an aircraft gas turbine engine has been simply the thrust it produces divided by its weight (T/W). While this measure is still appropriate, as the aircraft engine has matured, the rate of change of thrust to weight has begun to decrease and other factors such as costs have become increasingly important relative to performance. Therefore, it can be argued today that performance should have a broader, more comprehensive definition that includes other factors such as durability and reliability. Further, most modern military aircraft have some degree of "signature" treatment incorporated into the system. "Signature" is the radar (RF) or infrared (IR) signal that either emanates from or is created by an aircraft that allows its detection. The F-117 and B-2 systems are well known examples of low signature or "stealthy" systems. It is neither appropriate nor relevant to discuss signature control technology in detail here, but it is important to mention several points in connection with this subject. First, signature control is accomplished through a combination of the use of special design methods and materials with special physical properties. Second, any form of signature treatment adds weight and cost to the system. Third, the engine inlet and exhaust structures are a significant source of signature (both RF and IR) and require special attention if a given level is to be achieved. These areas of a system also represent the interface between the engine and the airframe and the responsibility for them typically is shared between the airframe and the engine manufacturers. Finally, retention of low signature usually requires additional maintenance and this also affects the affordability of a system.

REDUCING COSTS FOR AIRCRAFT GAS TURBINE ENGINES

Skira, Charles A., Wright Lab., USA; Philpot, Mike, Defence Research Agency, UK; Hauvette, Jacquesa, Societe Nationale d'Etudes et de Construction de Moteurs Aeronautiques, France; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 10p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Current military budget constraints are highlighting the cost issues in procuring and maintaining adequate defense forces. Aircraft and their engines are typical examples where costs are more and more expensive from one generation to the other. However, at the same time, it is recognized that the correlated increase in performance is necessary to keep the pace with the potential of adverse weaponry.

Due to the historic and dramatic changes in recent global events, the USA military services have been undergoing a drawdown in size. Since 1989, our military forces have been reduced by 30%. Over this period of declining budgets the DoD has slowed down the modernization of our forces in order to concentrate on maintaining force readiness and quality of life. However, by the year 2010, more than half of the US Air Force fighter fleet will consist of existing F-15's, F-16's and F-117A's, well beyond the expected service life of these systems. DoD and other defense departments must address the modernization of their forces to ensure readiness into the next century. This modernization will only be possible within the era of reduced defense budgets when the S&T community begins to focus on increasing the effectiveness of a user-identified capability while decreasing the costs of the necessary technology, and improving material through planned upgrades.

EUROFIGHTER 2000 is a single seat, aerodynamically unstable delta-canard fighter aircraft which embodies latest technologies in structures, systems, engine and avionics. The aircraft is powered by two EJ 200, a new engine specifically tailored to meet EF2000 mission requirements. Eurofighter Jagdflugzeug GmbH consortium is the prime contractor for the development of the complete weapon system. It is composed of the four national aircraft companies involved in the program, namely British Aerospace (BAe), Daimler-Benz Aerospace (DASA), Alenia (ALN) and CASA. Within this program, Alenia is tasked (among the other responsibilities) with the propulsion system development, that has been initially flight-tested by Alenia prototype DA3; it has been the first one fitted with the new EJ200 engines (built by Eurojet consortium). DA7, the second Alenia prototype, will be tasked (among other tasks like avionics/navigation testing) of final aircraft/engines performance verification. The first phase of the development programme has been successfully completed and the following phase, with the uprated engines standard, is already in progress. This paper summarizes: (1) the overall EF2000 flight test philosophy; (2) the approach to EJ200 engine flight test, including relight; (3) test organization, test methods, flight test instrumentation, data analysis, data management and (4) early test results.

Because of the high acquisition cost of military aircraft and the diminishing resources for new equipment acquisitions, many aircraft from NATO nations are likely to be kept in service longer than originally intended. The task of achieving life extension while ensuring the high levels of safety and reliability established in the past, will present formidable challenges. From the time an aircraft is put in service, compo-

nents from both the airframe and engine(s), undergo a process of damage accumulation which may take many forms and is influenced by usage severity. The long term effects of service induced damage are not always well understood, nor are they well documented, particularly for high time vehicles. The damage can affect both the performance and structural integrity of airframe and engine components. Designers and operators alike need to take into consideration this aging process for ensuring continued safety and reliability of the vehicles.

HANDLING QUALITIES ANALYSIS ON RATE LIMITING ELEMENTS IN FLIGHT CONTROL SYSTEMS

Hanke, Dietrich, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations; Feb 1, 1995, 18 p; In English; See also 19950024640; Copyright; Avail: CASI; A03, Hardcopy; A02, Microfiche

Rate saturation conditions caused by rate limiting elements (RLE's) in flight control systems can contribute to severe pilot induced oscillation. In order to gain more theoretical insight in this problem the paper deals with the development of rate limiter describing functions in order to establish a theoretical basis for open and closed loop handling qualities analysis in the frequency domain. Although rate limitation produces nonlinear system behaviour it could be shown that rate limiter describing functions could be applied to existing methods used in handling qualities analysis of pilot/aircraft systems. A new handling quality parameter, the rate limiter onset frequency, is defined as a measure of input amplitude and frequency. Here the onset frequency in reference to the system bandwidth could be a suitable parameter in defining handling qualities boundaries for flight control systems with RLE's. The response in amplitude and phase is presented for different types of input signals such as triangle and sinusoidal oscillations. Rate limiter cascading is considered, too. Further, the suitability of various existing handling quality criteria are compared with the RLE results especially with respect to PIO. Finally, the improvements in system behavior by applying an alternate control scheme (ACS), as proposed by A'Harrah, will be discussed.

In the last decade, Active Control Technology (ACT) has emerged from the realm of theory and modest experimental applications to full-scale use on production aircraft, while more elaborate forms of ACT are under test for the future production of aircraft. New technologies have been applied in military fighters to maximize maneuverability and agility, and in civil transports to reduce trim drag, lower pilot workload and improve riding qualities. During this symposium the status of Active Control Technology was assessed in light of the experience gained over the last decade. The symposium was organized around four sessions comprising 28 technical papers in all. These sessions focused on: Specifications for flight control design, Design and analysis methods, System integration and implementation of experience.

19950025569 Hoh Aeronautics, Inc., Lomita, CA, United States
THE ROLE OF HANDLING QUALITIES SPECIFICATIONS IN FLIGHT CONTROL SYSTEM DESIGN

Hoh, Roger H., Hoh Aeronautics, Inc., USA; Mitchell, David G., Hoh Aeronautics, Inc., USA; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 12 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The handling qualities specification should be an essential element of the flight control system design and testing for an active control technology (ACT) aircraft. This is a significant departure from previous conventional aircraft where handling qualities depended more on the configuration (tail size, control surface sizing, etc.). The necessity for incorporating the handling qualities specification into the flight control system design process has not been recognized by the industry, as evidenced by the fact that most of the ACT aircraft do not meet the requirements of the current handling qualities specification. This has resulted in excessive phase lag in the flight controls, and numerous cases of pilot induced oscillation. This paper reviews key handling qualities criteria for ACT aircraft as well as lessons that should be incorporated into specification upgrades and flight control design efforts.

19950025570 Gibson (J. C.), Saint Annes, United Kingdom
THE PREVENTION OF PIO BY DESIGN

Gibson, J. C., Gibson (J. C.), UK; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 12 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Control problems caused by poor pilot-aircraft closed loop characteristics have existed for as long as aircraft have been flown. The majority of them have been the result of excessive response amplitudes and phase lags conflicting with simple stability margin requirements. Their solutions have been rather straightforward and often amount to the provision of K/S-like responses, or sufficiently similar, within the bandwidths of interest. Most high order Pilot Induced Oscillation (PIO) problems have been introduced, not by more complex fly by wire control laws, but by unnecessary lags or sometimes by excessive gain placed between the pilot and the response. The pilot is forced to operate in a region of excessive phase lag and response gain, typically with the impression that the aircraft is not actually responding to the commands. The solutions address the provision of adequate stability margins in much the same way as in earlier problems. The high order PIO problem is identified in the open loop attitude behavior in the uniquely defined PIO frequency region, in which the response lags the stick by 180 degrees or more. It is not necessary to model the pilot, who is found to operate in a synchronous manner with the attitude oscillation. The dominant feature in this is the rate zero crossing which acts to trigger the reversals of the control input. The input itself may take the form of a sinusoid, a relay switching action, or a mixture of the two. A number of simple criteria can be applied to control law design which have been found to ensure the prevention of high order PIO. The existence of a PIO problem can be identified with great certainty before flight by specific test methods, which should be applied with rigor no matter how much confidence exists in the design methods. Finally, it is crucial for all concerned to understand that if the underlying problem is there, no matter how extreme the pilot inputs may have to be to excite it, then it can be expected to happen in flight. It will be impossible to prevent it by pilot briefings.

EXPERIENCES WITH ADS-33 HELICOPTER SPECIFICATION TESTING AND CONTRIBUTIONS TO REFINEMENT RESEARCH
 Ockler, C. J., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Pausder, H.-J., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 20 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The introduction of Active Control Technology in rotorcraft created the need for new handling qualities requirements. In response to this, a new helicopter handling qualities specification was developed under the leadership of the U.S. Army and published as Aeronautical Design Standard 33 (ADS-33). Since its introduction, research has been conducted to expand the handling qualities database on which ADS-33 is based. This paper presents DLR contributions to this research. A standard BO 105 was used to evaluate the applicability and repeatability of the current ADS-33C criteria in forward flight. As a result of this study, some data gaps were recognized and the criteria that need further verification were identified. The in-flight simulator ATHeS was used for an investigation of the effects of bandwidth and phase delay and pitch-roll coupling on helicopter handling qualities in a high gain slalom tracking task. Results are shown that indicate a need to more tightly constrain the phase delay for the roll axis than in the current ADS-33 requirements. For the pitch-roll coupling criterion it is shown that although the format of the current ADS-33 requirements is valid for control and rate coupling, it cannot be used for coupling types typical of actively controlled helicopters. A frequency domain criterion that offers more comprehensive coverage of all types of pitch-roll coupling is proposed.

The flight control system of the Lavi Multimission fighter is described. The control laws design philosophy is given along with the control laws development, the flying qualities requirements and the final structure of the pitch axis (DFCS). The simulation phase is covered along with special control laws features. The question 'how does the Lavi fly?' is addressed. Problems uncovered during flights, and solutions found, are detailed and the flying qualities data are given. Finally, the program status is explained.

This paper discusses an application of several robust control methodologies such as $H(\infty)$ optimal control, micro-synthesis and gain scheduling via linear fractional transformations applied to a flight control system. To illustrate the approach, a design model for the short period approximation of the Cessna Citation 500 has been chosen, for which certain handling quality requirements have to be met over a large set of operating conditions. For all these methods, the design framework remains the same, only the system 'norm' changes to the object to be minimized. The paper shows how these methods work and illustrates the features of the new approach.

EVALUATION OF THE TECHNIQUES OF FUZZY CONTROL FOR THE PILOTING AN AIRCRAFT EVALUATION DES TECHNIQUES DE CONTROLE FLOU POUR LE PILOTAGE D'AVION

Imbert, N., Office National d'Etudes et de Recherches Aérospatiales, France; Piquerau, A., Office National d'Etudes et de Recherches Aérospatiales, France; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 10 p; In French; See also 19950025568; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

The characteristic of a fuzzy controller is to use a knowledge expressed in natural language in the forms of expert rules to calculate the value of the control starting from the numerical information from the sensors. The implementation of such a pilot requires the interpretation of the numerical field symbolically and reciprocally. This is carried out by the use of fuzzy assemblies. The associated theory allows starting from consideration of precise measurement, the whole of the stated expert rules, and choice of suitable operators to deduce a value from control. It results in a particular structure of the fuzzy controllers, whose main characteristics are the subject of the first part of the presentation. The implementation on the example of the longitudinal pilot control of an aircraft is then presented. Two approaches were adopted: the first uses the rules of manual piloting formulated in natural language by the 'experts' who are the pilots. The second uses the laws resulting from a conventional autopilot to build rules of piloting. The results are presented in the perspective from a comparison between the two types of controllers, conventional or fuzzy.

THE CONTROL SYSTEM DESIGN METHODOLOGY OF THE STOL AND MANEUVER TECHNOLOGY DEMONSTRATOR

Moorhouse, David J., Wright Lab., USA; Citurs, Kevin D., McDonnell-Douglas Aerospace, USA; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 11 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper documents the development of a full-envelope Integrated Flight/Propulsion Control system. A combination of classical and multivariable design methodologies was used, including a unique

inverse procedure to produce second-order equivalent systems meeting specified flying qualities requirements. The implementation was based on a rational choice between the two methodologies. It is suggested that a parallel design approach in the beginning will produce efficient convergence on a practical optimum design. Finally, all control law revisions should be done analytically and only evaluated by simulation. Regardless of the design technique used, the process begins by specifying detailed design guidelines selected to meet the intent of MIL-F-8785C. Once the designs were complete and analyzed based on the design guidelines, manned flight simulation was used only to validate and demonstrate the flying qualities achieved prior to flight test. Problems encountered during simulation or flight testing were addressed first by reviewing the original design guidelines and evaluating the success achieved in implementing them.

CONTROL LAW DESIGN USING H-INFINITY AND MU-SYNTHESIS SHORT-PERIOD CONTROLLER FOR A TAIL-AIRPLANE

Mangiacasale, L., Aeronautica Macchi S.p.A., Italy; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 11 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The recently developed methods $H(\infty)$ and μ -Synthesis are used in the design of a control law for a tail controlled unstable airplane. The design procedure has been applied with success and seems to be very promising in order to solve control design problems in real applications. The $(H(\infty) + \mu)$ controller, characterized by a very large order (namely 34th), has been successfully reduced to one having order 5th with a very low decay in the overall performance. The reduced-order controller meets all the servo technical specifications demanded to the full-order one. At present it is under test as part of a 6-DoF simulation program to verify its real robustness in face of structured and unstructured perturbations.

MODEL FOLLOWING CONTROL FOR TAILORING HANDLING QUALITIES: ACT EXPERIENCE WITH ATTHES

Bouwer, Gerd, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Vongruenhagen, Wolfgang, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Pausder, Heinz-Juergen, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 15 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

In-flight simulators will play an important and unique role in the development process of future helicopter systems and in generating credible handling qualities data which establish design guides for the integrated helicopter systems including sophisticated cockpit technologies and high authority control systems. The Institute for Flight Mechanics of DLR has developed the helicopter in-flight simulator ATTHes (Advanced Technology Testing Helicopter System) which is based on a BO 105 helicopter. The testbed is equipped with a full authority nonredundant fly-by-wire control system for the main rotor and a fly-by-light system for the tail rotor. In the simulation mode the testbed requires a two-man crew, a simulation and a safety pilot. The onboard computer system consists of two computers to which are assigned the separated tasks, data collection and digital control system. With the implemented software structure the flexibility is achieved to change the control laws without any changes in the real time process. Before undergoing any flight test with a new or modified control system, a real-time hardware/software-in-the-loop ground-based simulation has to be successfully performed. For the purposes of in-flight simulation an explicit model following control system was developed and the model following performance was evaluated in flight. This control system is composed of a dynamic feedforward, based on an extended model of the host helicopter, and an optimized feedback control system. The capability and flexibility of ATTHes has been demonstrated in different test programs which have been related

to the use of the testbed for test pilot training, handling qualities research, helicopter simulation, and control law design and evaluation including automatic navigation and hover position hold.

Two X-29A aircraft were flown at the NASA Dryden Flight Research Center over a period of eight years. The airplanes' unique features are the forward-swept wing, variable incidence close-coupled canard and highly relaxed longitudinal static stability (up to 35-percent negative static margin at subsonic conditions). This paper describes the primary flight control system and significant modifications made to this system, flight test techniques used during envelope expansion, and results for the low- and high-angle-of-attack programs. Throughout the paper, lessons learned will be discussed to illustrate the problems associated with the implementation of complex flight control systems.

ADVANCED GUST MANAGEMENT SYSTEMS: LESSONS LEARNED AND PERSPECTIVES

Koenig, R., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Hahn, K.-U., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Winter, J., Dornier Luftfahrt G.m.b.H., Germany; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 17 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Aircraft operations at low altitudes often are affected by strong gusts and turbulence producing additional aerodynamic forces and moments. This results in extra aircraft accelerations and therefore in an unpleasant impact on passenger comfort and pilot workload as well as in extra structural loads. Active Control Technology is able to suppress these effects partly. The knowledge about the potential for improvement, the parameters of influence and the performance requirements for such gust alleviation systems is still quite small. Since the mid-seventies Dornier and DLR (Institute of Flight Mechanics) have been working together on BMFT programs developing systems to improve the ride quality in gusty weather. The developed Open-Loop Gust Alleviation System OLGA was investigated through dynamic wind tunnel experiments and flight-tested onboard the experimental aircraft Do 128 TNT. This research was continued by DLR developing the Load Alleviation and Ride Smoothing System LARS using the modified VFW 614 aircraft ATTAS (Advanced Technologies Testing Aircraft System). The Deutsche Aerospace Dornier Luftfahrt GmbH has concentrated on simulation studies for their aircraft types Do 228 and Do 328. The presented paper provides a brief description of the advantages of overall gust management systems considering lift, drag and pitch control. The following topics will be presented in detail: (1) the basic flight mechanics of gust load alleviation; (2) the design of integrated gust management systems; (3) simulation and flight test results; and (4) lessons learned and general perspectives.

The use of unmanned air vehicles (UAV) in support of the Navy from small ships to fulfill tasks such as reconnaissance of large areas will succeed only if the user gains a high amount of confidence in the reliable operation of such a system, especially during the take off and landing phase. Take off from and landing on small landing pads on aviation facility ships in all-weather conditions prefer the application of VTOL-UAV's (Vertical Take Off and Landing) with a coaxial rotor system. Manual take off and landing procedures which have to be applied during operational service both at day time and at night under all-weather conditions and ship motions overtax the service personnel already at low sea states. This fact requires automatic take off and landing procedures. The German Ministry of Defence commissioned Dornier (DASA) in November 1990 with the development, test and demonstration of an automatic take off and landing system on the basis of the Gyrodyne QH-50 drone helicopter in order to prove the feasibility of such a system in general. The essential ship and sea state dependent motions of the landing pad - roll, pitch and heave - were simulated with a ship deck simulator. The customer's requirement consisted of ten automatic take offs and landings of the UAV from a 4 by 4 meters landing pad. The test and demonstration phase was performed on the airfield of Friedrichshafen in the presence of experts from several NATO-Countries by the end of 1991.

THE FCS-STRUCTURAL COUPLING PROBLEM AND ITS SOLUTION

Caldwell, B. D., British Aerospace Defence Ltd., UK; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 13 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Implementation of ACT in aircraft is now almost routine, and often essential in realizing performance requirements. However, unless a proactive and thorough approach is taken to ensuring that the effects of the flexibility of the airframe structure and its interaction with the FCS (Flight Control System) are analyzed and accounted for, costly development delays and control system redesigns may ensue. This paper is intended to discuss the basis of the phenomenon referred to at BAe Warton as FCS-Structural Coupling, the evolution of the methodology evolved at Warton to ensure freedom from its effects, and the development directions required to advance the state of art in this field.

A survey on the structural relevant applications of Active Control Technology is presented. The benefits and disadvantages of various active control systems for transport and fighter aircraft are discussed. The problem of adverse structural coupling is addressed and possible solutions are outlined. The Smart Structure Technology offers new applications for active control technology, but to exploit the full potential of this technology multidisciplinary design methods have to be improved.

DIGITAL AUTOPILOT DESIGN FOR COMBAT AIRCRAFT IN ALLENIA

Tonon, Aldo, Alenia Aeronautica, Italy; Belluati, Pier Luigi, Alenia Aeronautica, Italy; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 13 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

ALLENIA - Aeronautica has been involved in Digital Autopilot design for the AMX and EF 2000 programs. The AMX is a subsonic attack aircraft whose Flight Control System is based on Fly-by-wire technology, incorporating an Hybrid Analog and Digital Flight Control Computer for Control and Stability augmentation in pitch, roll and yaw axes, which guarantees the aircraft capability of full performance; in addition the Flight Control System has also a conventional mechanical back-up in the pitch and roll axes, which guarantees aircraft safe re-entry after failure of both hydraulic and both electrical circuits. The paper deals with the development history of the AMX autopilot through design to flight test. In particular the paper addresses the design to specification relationship, the system development and clearance process and the flight test results. The EF 2000 programme is an international development for an agile, highly unstable Fly-by-Wire Air Superiority fighter. Within the EF 2000 consortium ALLENIA has the responsibility for Basic Autopilot design. This design, currently in the early stages of development, poses peculiar problems due to the interaction of Autopilot (external) feedback loops and the basic stabilization (inner) loops. The paper address these peculiar aspects in conjunction with the specific design methodologies applied.

EXPERIMENTAL AIRCRAFT PROGRAMME (EAP): FLIGHT CONTROL SYSTEM DESIGN AND TEST

McCuish, A., British Aerospace Defence Ltd., UK; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 14 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The objectives of the Experimental Aircraft Programme were to demonstrate various technologies relevant to a future combat aircraft within the rigors imposed by having to achieve flight clearance and demonstration. Prime areas for demonstration, among others, were modern cockpit displays, avionics systems integration, advanced material construction, advanced aerodynamics and active flight control. Nearly all future combat aircraft will have an unstable basic airframe due to the advantages that are accrued: smaller, lighter, aerodynamically more efficient, etc. Necessary to such an aircraft is a full time active control system. This paper outlines the philosophy and method taken to design the flight control laws and relates their development through the life of the programme. The experience gained from the three phase, 259 flight test programme is summarized. The success of the flight programme has provided a wealth of experience from the operation of the aircraft. In particular, and most impressive to the pilots, was the carefree handling capability; this was considered remarkable. A further success was the complete absence of pilot induced oscillation (PIO) tendency throughout the whole of the flight programme.

AN INVESTIGATION OF PILOT INDUCED OSCILLATION PHENOMENA IN DIGITAL-FLIGHT CONTROL SYSTEMS

Flynn, William A., Air Force Flight Test Center, USA; Lee, Robert E., Air Force Flight Test Center, USA; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 6 p; In English; See also 19950025568; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper summarizes the results of a technical review of pilot induced oscillations (PIO) in aircraft equipped with digital flight control systems. A review of the causes of PIO, the specific interaction of

digital flight control systems, and an evaluation of the flight control development process was conducted. The paper discusses the highlights of the technical review and the recommendations for future development of flight control systems to reduce the occurrences of handling qualities problems in general and PIO in particular.

FLIGHT DEMONSTRATION OF AN ADVANCED PITCH CONTROL LAW IN THE VAAC HARRIER AIRCRAFT

Fielding, C., British Aerospace Defence Ltd., UK; Gale, S. L., Defence Research Agency, UK; Griffith, D. V., Defence Research Agency, UK; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 12 p; In English; See also 19950025568; Sponsored by UK Ministry of Defence; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

'Vectored thrust Aircraft Advanced flight Control' (VAAC) is a UK project, sponsored by the Ministry of Defence and managed by the Defence Research Agency (DRA). The project is investigating, through ground-based simulation and flight test on the VAAC Harrier research aircraft, the low speed flight control, handling and cockpit display concepts applicable to an aircraft replacing the Harrier. As part of the project, British Aerospace Defence Limited have designed a revolutionary two-inceptor pitch plane control law for assessment on the project aircraft. This Control Law has now been flight tested and further developed 'in-flight' by the DRA, culminating in a series of successful flight demonstrations to guest pilots. During the latter stages of flight testing the Control Law was modified to allow single-inceptor operation. Flight testing has shown that both the two- and single-inceptor control strategies result in a large reduction in pilot workload, when compared with the VAAC Harrier's three-inceptor arrangement, during the transition from wing-borne to jet-borne flight and hover. This paper describes the Control Law's evolution from initial concept through to the results obtained from flight testing.

ADVANCED FLIGHT CONTROL TECHNOLOGY ACHIEVEMENTS AT BOEING HELICOPTERS

Landis, Kenneth H., Boeing Defense and Space Group, USA; Dabundo, Charles, Boeing Defense and Space Group, USA; Davis, James M., Boeing Defense and Space Group, USA; Keller, James F., Boeing Defense and Space Group, USA; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 16 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

Over the last two decades, flight control system requirements have been in a state of transition. Rotary wing missions have become more demanding, requiring vehicle management systems capable of conducting highly aggressive missions under night / adverse-weather conditions in severe electromagnetic environments. The digital, fly-by-wire / optics control system technologies developed at Boeing Defense and Space Group, Helicopters Division to meet these air vehicle requirements are overviewed. These technologies, which integrate digital multimode control laws and sidestick controllers within redundant-reconfigurable architectures, provide the rotorcraft capabilities required for the 21st century. The advances in flight control design, as developed during various technology demonstrator programs and applied in production of the V-22 Osprey tiltrotor and the RAH-66 Comanche scout / attack helicopter, are summarized.

PRACTICAL EXPERIENCES IN CONTROL SYSTEMS DESIGN USING THE NCR BELL 205 AIRBORNE SIMULATOR

Baillie, Stewart W., National Research Council of Canada, Canada; Morgan, J. Murray, National Research Council of Canada, Canada;

Goheen, Kevin R., National Research Council of Canada, Canada; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 12 p; In English; See also 19950025568; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

The objective of this paper is to describe a variety of examples of control system design and application on the NRC Bell 205 Airborne Simulator. For background, this paper will first examine the physical characteristics of the Bell 205 and the mathematical models which have been developed to describe them. The paper then reviews the classical control design techniques which have been used to develop high bandwidth rate and attitude response type systems on the aircraft, and describes the empirically determined fixes which have become standard elements of these types of systems. To complete the paper, two sections will deal with application of modern control theories; the first describes a limited effort to develop a translational rate command system using a six degree of freedom model of the Bell 205 and a publicly available software package, MATLAB/Simulink. The second modern control theory section deals with a more detailed study performed in collaboration with Carleton University and supported by DND/CRAD to devise modern control theory controllers for the Bell 205. All discussions of the paper are substantiated with actual in-flight validation data to clearly demonstrate design successes and failures.

FLYING QUALITIES OF CIVIL TRANSPORT AIRCRAFT WITH ELECTRICAL FLIGHT CONTROL LES QUALITES DE VOL DE AVIONS DE TRANSPORT: CIVIL A COMMANDES DE VOL ELECTRIQUES

Chatrenet, D., Aerospatiale, France; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 5 p; In French; See also 19950025568; Copyright; Avail: CASI; A01, Hardcopy; A04, Microfiche

This conclusion to the conference covers the flying qualities and flight control systems (FCS) of transport aircraft equipped with electrical flight control systems, as seen by Aerospatiale. A retrospective look at the related technological developments over the past 25 years precedes a comparison between the Airbus A340 and A320. The main points in the differences between the FCS in the A320 and the A340 are associated with the compensation effects of the more flexible structure of the A340, its design for long-range ('minimum drag'), and the inherent limitations in take-off performance.

PILOT INDUCED OSCILLATION: A REPORT ON THE AGARD WORKSHOP ON PIO

McKay, K., British Aerospace Defence Ltd., UK; AGARD, Active Control Technology: Applications and Lessons Learned; Jan 1, 1995, 10 p; In English; See also 19950025568; Copyright; Avail: CASI; A02, Hardcopy; A04, Microfiche

Instability of the pilot/airframe combination has been a problem from the beginning of manned flight. The rapid advances made in aviation following the Second World War greatly increased the incidence of PIO problems and led to a large amount of research and development work aimed at understanding and mitigating these difficulties. Criteria and requirements were developed which could be used in design to obtain satisfactory PIO qualities. Nevertheless, in spite of all this work, and even with the great flexibility in modern control technologies available to the designer, PIO problems still often occur with new aircraft; in fact it is the power and responsiveness of modern control systems which makes them susceptible to various 'non-linear' effects such as time delays, rate limits, actuator saturation, etc., leading to unexpected PIO difficulties. With current experience, it is clear that a universal solution of the PIO problem still evades the engineering community. The cost of these problems in programme delay and financial terms is significant. The gathering together of specialists to discuss this problem, from their various points of view, has led to positive gains in the state of knowledge regarding PIOs; it has provided

a significant step toward their elimination and contributed to the avoidance of PIO associated programme costs and penalties. This paper provides an overview of the results from the Workshop. Fuller details are to be published by AGARD in the proceedings of the Conference and Workshop in the near future and in a separate Advisory Report.

FUNCTIONAL DEVELOPMENT AND FIELD TEST OF CASSY: A KNOWLEDGE-BASED COCKPIT ASSISTANT SYSTEM

Onken, R., Universitaet der Bundeswehr Muenchen, Germany; AGARD, Knowledge-Based Functions in Aerospace Systems; Nov 1, 1995, 22 p; In English; See also 19960012290; Avail: CASI; A03, Hardcopy; A02, Microfiche

This paper presents the functional concept and development of the cockpit assistant system CASSY, based on basic requirements for effective man/machine interaction. This system was developed in order to enhance flight safety and mission effectiveness. The time has come that cockpit systems will no longer be designed on a vague basis of specifications. The advances in technology provide the necessary basis to systematically reflect requirements for human-centered automation into clear-cut specifications and system design. CASSY is developed as a knowledge-based system. It has been extensively tested in flight simulators as well as field tested in the ATTAS (Advanced Technologies Test Aircraft System) of the DLR. Some of the results of these flight trials will be presented in this paper. The development was conducted by the University of the German Armed Forces, Munich with some support by DASA.

This paper aims at describing first lessons learnt in terms of engineering guidelines and development methodology within the french project called 'Copilote Electronique' of an Electronic Crew Member System. This project is lead by Dassault Aviation with the support of French official services (DRET, STTE) and involves several industrial and scientific partners (SAGEM, Dassault Electronique, Matra Defense, Sextant Avionique, IMASSA). The French 'Copilote Electronique' project started in 1986 through various preliminary studies and since 1994 it has taken a larger scale under the form of an exploratory development. Before the start of this development, advantages and drawbacks of existing software engineering or knowledge acquisition methodologies were compared. Emphasis was put on ergonomics design rules and on a project life cycle adaptation aiming at insuring better responses to pilots demands and fears. Building on the first year experience of the exploratory development phase of the Copilote Electronique project, we express confidence for successful operational evaluations.

The strategy used at Aerospatiale when performing flight clearance tests of modern civil aircraft equipped with Electronic Flight Control Systems (EFCS), particularly if the aircraft is prone to adverse interactions between the structural modes of the aircraft and the flight control system, is presented in the paper. Because of the potential for

adverse interactions it is shown that, in addition to the classical flutter tests, it is necessary to check the in-flight dynamic behavior of the aircraft with EFCS operating at various flight conditions. The following topics are discussed in the paper: the choice of excitation devices; the description of recorded parameters; the importance of preflight analyses; the choice of flight conditions and configurations to be tested; and the correlation between the analytical model and the flight test modal analysis results. The paper also provides examples of aeroservoelastic flight test results.

The design of notch filters is based upon a model of the aircraft describing the coupled flight dynamic, flight control dynamics and structural dynamic behavior, and on ground and in flight structural coupling tests. The paper outlines design procedures, design and clearance requirements, correlation between model predictions and structural coupling tests and model update for on ground and in flight.

PARAMETRIC IDENTIFICATION OF TRANSONIC UNSTEADY FLOW CHARACTERISTICS FOR PREDICTING FLUTTER OF FIGHTER AIRCRAFT WITH EXTERNAL STORES

Meijer, Jos J., National Aerospace Lab., Netherlands; Cunningham, Atlee M., Jr., Lockheed-Fort Worth Co., USA; Feb. 1996; 16p; In English; See also 19960022326; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

An analysis of steady wind tunnel data, obtained for a fighter type aircraft, has indicated that shock-induced and trailing-edge separation play a dominant role in the development of Limit Cycle Oscillations (LCO) at transonic speeds. On the basis of these data a semiempirical LCO prediction method was developed. Its preliminary version has been applied to several configurations and has correctly identified those which have encountered LCO. It has already shown the potential for application early in the design process of new aircraft to determine and understand the nonlinear aeroelastic characteristics. In the present paper this method is upgraded on the basis of results of unsteady wind tunnel force and pressure measurements obtained from on oscillating fighter type wings. In particular, an aerodynamic nonlinear state-space model embedded in the LCO prediction method will be demonstrated. The developed aerodynamic model is a semi-empirical, unsteady, nonlinear model which makes use of these experimental steady and unsteady data. Validations are presented for various fighter configurations by comparing calculated LCO results with information from flight test data.

VARIABLE STABILITY IN-FLIGHT SIMULATOR TEST AIRCRAFT (VISTA)

Buehler, Kurt, Air Force Flight Test Center, USA; Reynolds, Phil, Calspan Corp., USA; Markman, Steve, Wright Lab., USA; Hellmann, Gary, Wright Lab., USA; Apr. 1996; 10p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The VISTA is the USA (US) of America's next generation in-flight simulator, replacing the aging NT-33. The VISTA is an F-16D with the Israeli Peace Marble 2 configuration. The flight control system has

been extensively modified to create a state of the art in-flight simulator. The VISTA Phase 2 Development, Test and Evaluation (DT&E) at the Air Force Flight Test Center (AFFTC) started in July 1994 and was completed in January 1995. The flight test team consisted of personnel from the USA Air Force (USAF), Lockheed Fort Worth Company, and Calspan Corporation. The VISTA flew 62 test sorties for a total of 138 flight test hours at the AFFTC meeting or exceeding all design specifications. The VISTA is owned by Wright Laboratory's (WL) Flight Dynamics Directorate. The Calspan Corporation maintains and operates the VISTA for WL. Using the aerodynamic, mass, inertia, and controller characteristics, and the flight control laws of other aircraft, the VISTA can simulate the aircraft 'in-flight' determining the flying qualities and handling characteristics. The USAF and Navy Test Pilot Schools utilize the VISTA in their curriculum. The VISTA is available to support the USAF, other branches of the US Department of Defense, commercial aircraft development, National Aeronautics and Space Administration (NASA), and foreign military aircraft development programs. This paper presents a brief summary of the development of the VISTA, the hardware and software modifications that were made to create the VISTA, the VISTA Phase 2 flight test plan and results, and discusses the future direction of in-flight simulation.

IMPROVED ENGAGEMENT ENVELOPE OF A TACTICAL MISSILE WITH AN INTEGRAL ROCKET/RAMJET ENGINE

Lauzon, M., Defence Research Establishment Valcartier, Canada; Subsystem Integration for Tactical Missiles (SITM) and Design and Operation of Unmanned Air Vehicles (DOUAV); Nov. 1996; 17p; In English; See also 19970018626; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A trade-off study on mission effectiveness identified definite benefits of the solid fuel integral-rocket-ramjet engine over the solid rocket motor for a medium-range air-to-air tactical missile. A six-degrees-of-freedom trajectory simulation model was first developed to assess the performance and operating envelope of the solid rocket motor and the ramjet engine for tactical air-to-air missile applications. The 6DOF simulation code includes a fully algebraic model for ramjet propulsion, a model for missile guidance based on the law of proportional navigation and a three-degrees-of-freedom target trajectory model. It can be used to evaluate missile kinematic performance and effectiveness against a maneuvering target. Results show that ramjet propulsion improves three important performance characteristics of a missile, namely, the time-of-flight (average velocity), maximum range and end-game maneuverability for longer range missions. The solid rocket motor, with its high thrust output and low burn time, gives the tactical missile a higher average velocity and hence a better maneuverability for shorter range engagements. A missile time-of-flight envelope with a non-maneuvering target at 10 km altitude shows that the IRR missile offers a time-of-flight advantage for launch ranges greater than 25-35 km and improves the missile maximum range capability by 40%. The IRR engine also extends the 3 g(sub n) maneuverability boundary by 50% in slant range.

CONTROL OF A SUPERSONIC AIR TO GROUND MISSILE WITH VERY LIGHTLY DAMPED BENDING MODES

Friang, J. P., Aerospatiale Missiles, France; Bonnet, J. P., Aerospatiale Missiles, France; Duc, G., Ecole Supérieure d'Electricité, France; Nov. 1996; 16p; In English; See also 19970018626; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

In this paper, an autopilot is designed to control a missile with very lightly damped bending modes, using the loopshaping $H(\infty)$ design procedure of McFarlane and Glover. Robustness in the face of large modelling uncertainties (including parameter and bending modes) is then investigated using real μ -analysis. The autopilot of the Bank to Turn (BTT) missile developed by AEROSPATIALE

(French Aerospace Industrial National Company) is finally validated on a non linear simulator: this will show the performances and the robustness of our design.

Since the earliest days of manned flight, designers have sought to assist the pilot in the performance of tasks by using stick and feel systems to bring these tasks within the bounds of human physical capabilities. This volume describes stick and feel systems in two parts. Part one describes the technologies which have been developed throughout the history of 20th Century aviation. Part two describes how modern systems dynamics interact with the human pilot. It is hoped that the design lessons and approaches outlined in this volume will contribute to a better understanding and appreciation of the importance of force-feel system design in aircraft/rotorcraft flight control.

This paper describes research being undertaken by GKN Westland Helicopters and the UK Defence Research Agency (DRA) to examine enhanced augmentation of helicopter flight control systems. Current research is targeted at mechanical primary flight control systems with limited authority automatic flight control systems (AFCS) with a view towards early application as a retrofit to in-service helicopters or new versions of existing helicopters.

ACTIVE CONTROL OF AEROMECHANICAL STABILITY

Krysinski, Tomasz, Eurocopter France, France; Apr. 1997; 26p; In English; See also 19970025403; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper presents the active control of aeromechanical stability as a powerful means of simplifying rotor design in future helicopters. The mathematical simulation model is presented and the results are compared to flight test data. The active control of ground resonance was fully validated with flight tests in the Super Puma Mk2 helicopter which behaved in a highly efficient and robust manner. An active control strategy is suggested for air resonance and drive train stability, a validation with flight tests is forecast in the near future. The proposed controls are simple and easy to integrate in a conventional Flight Control System (FCS). The actuators available in the current FCS are sufficient as far bandwidth required for active control of aeromechanical stability is concerned.

The hands and eyes busy situation and high workload as is normally the case in a fighter cockpit require a natural means of communication between operator and system. Voice is an obvious means of communication, however the adverse cockpit conditions deteriorate the speech signal in such a way that automatic recognition of spoken commands is difficult. In this study the performance of a voice controlled cockpit was investigated. An automatic speech recognizer was integrated in the control system of a F-16 simulator. The performance was evaluated during representative operational simulated flights. A similar study was performed by Prevot and Onken (1995). The results indicate that a flexible syntax of the commands is required. The recognition performance (75%) of the connected command strings was not good enough to accommodate the pilots. From flight tests a representative spontaneous speech data base was collected for further improvements.

A COMPARISON OF PRESSURE MEASUREMENTS BETWEEN A FULL-SCALE AND A 1/16-SCALE F/A-18 TWIN TAIL DURING BUFFET

Moses, Robert W., NASA Langley Research Center, USA; Pendleton, Ed, Wright Lab., USA; Feb. 1997; 12p; In English; See also 19970029334; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

In 1993, tail buffet tests were performed on a full-scale, production model F/A-18 in the 80-by-120 Foot Wind Tunnel at NASA Ames Research Center. Steady and unsteady pressures were recorded on both sides of the starboard vertical tail for an angle of attack range of 20 to 40 degrees and at a sideslip range of -16 to 16 degrees at freestream velocities up to 100 knots (Mach 0.15, Reynolds number 1.23×10^6 (exp 7)). The aircraft was equipped with removable leading edge extension (LEX) fences that are used in flight to reduce tail buffet loads. In 1995, tail buffet tests were performed on a 1/16-scale F-18 A/B model in the Transonic Dynamics Tunnel (TDT) at NASA Langley Research Center. Steady and unsteady pressures were recorded on both sides of both vertical tails for an angle-of-attack range of 7 to 37 degrees at freestream velocities up to 65 knots (Mach 0.10). Comparisons of steady and unsteady pressures and root bending moments are presented for these wind-tunnel models for selected test cases. Representative pressure and root bending moment power spectra are also discussed, as are selected pressure cross-spectral densities.

IMPACT OF ELECTRONIC FLIGHT CONTROL SYSTEM (EFCS) FAILURE CASES ON STRUCTURAL DESIGN LOADS

Besch, H.-M., Daimler-Benz Aerospace A.G., Germany; Giessler, H.-G., Daimler-Benz Aerospace A.G., Germany; Schuller, J., Daimler-Benz Aerospace A.G., Germany; Feb. 1997; 10p; In English; See also 19970029334; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

For structural design loads, the most relevant benefits of the advent of fly-by-wire and digital flight control systems are drawn from more sophisticated control of the aircraft and from the flight envelope protection functions. In parallel, rarely recognized even by the engineering community, the number of failure cases to be considered in A/C design is significantly increasing due to the growing complexity of the systems, eroding the aforementioned benefits. The monitoring system, designed to detect and to trigger removal of failure cases, can ease but not nullify the impact of failure cases on loads. Experience gained in the structural design of an A/C with fly-by-wire and digital flight control system is summarized, highlighting the necessity to cover system failures in calculating structural design loads. The current requirements for structural design of EFCS A/C are explained, by giving several examples of system failures of the new EFCS

technology, it will be demonstrated how the requirements are met, whereby the influence on structural loads is especially emphasized. Generic system-failure cases (software/hardware) having an influence on structural loads, are runaway, jamming and oscillation of control surface(s), the latter we call Oscillatory Failure Cases (OFC). OFC's cause significant component loads and can cause resonance phenomena which may generate excessive loads for poorly damped rigid body and flexible modes. This motivated the research programme Oscillatory Failure Case Identification System (OFIS) which, as a future component of the common Monitoring Systems, aims at detection of OFC's in time. We describe the current status of OFIS that exploits the specific properties of OFC for detection enhancement. Furthermore, by investigating the inverse effect, namely, that structure loads have an influence on system layout (or modification), this presentation will underline the necessity, mentioned above, of co-operation between all disciplines in modern aircraft design.

INVESTIGATIONS ON HANDLING QUALITIES AND AERODYNAMIC CHARACTERISTICS OF EUROFIGHTER 2000 AT DAIMLER-BENZ AEROSPACE FLIGHT TEST CENTRE

Oelker, Hans-Christoph, Daimler-Benz Aerospace A.G., Germany; Muthsam, Erfried W., Daimler-Benz Aerospace A.G., Germany; Dec. 1997; 12p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Currently the development flight test evaluation of EURO-FIGHTER 2000 is under way. The present paper emphasizes on analysis methods for flight mechanical and aerodynamical evaluation suitable for a very agile, highly unstable fighter aircraft at DAIMLER-BENZ AEROSPACE flight test centre. Methods are summarized and illustrated with some representative results. Analysis methods in the time domain such as simulation of flown manoeuvres and in the frequency domain such as Z-transformation and Fourier analysis methods for system stability evaluations are presented. DASA's aerodynamic parameter identification method is presented. It resembles a unique equation decoupling approach to cope with the problems arising from the analysis of unstable aircraft. Representative results are given, which demonstrate the analysis capabilities of the presented methods.

FLIGHT TESTING OF MANUAL FLIGHT CONTROL FUNCTIONS FOR A SMALL TRANSPORT AIRCRAFT (PROJECT ATTAS-SAFIR)

Heintsch, Thomas, Daimler-Benz Aerospace A.G., Germany; Luckner, Robert, Daimler-Benz Aerospace A.G., Germany; Hahn, Klaus-Uwe, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Dec. 1997; 10p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In a technology programme DASA has developed Flight Control Laws (FCL) for an electronic flight control system of a small transport aircraft (100-seater). In a cooperation between DASA and DLR, the flight control functions were tested on DLR's VFW614/ATTAS test aircraft. This paper gives an overview of the flight control law development and testing within the SAFIR (Small Airliner Flight Control Law Investigation and Refinement) flight test project. Design objectives of the flight control system for the 100-seater are reviewed, a system overview is given, the flight control law functions are briefly explained and the development process is described. The testing procedure comprises the Small Airliner Flight Investigation and Refinement (SAFIR) experiment integration into the ATTAS test system, the definition of the flight tasks, the flight testing and the evaluation of the flight test results.

EVALUATION OF HIGH-ANGLE-OF-ATTACK HANDLING QUALITIES FOR THE X-31A USING STANDARD EVALUATION MANEUVERS

Stoliker, Patrick C., NASA Dryden Flight Research Center, USA; Bosworth, John T., NASA Dryden Flight Research Center, USA; Dec. 1997; 24p; In English; See also 19980035004; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The X-31A aircraft gross-acquisition and fine-tracking handling qualities have been evaluated using standard evaluation maneuvers developed by Wright Laboratory, Wright Patterson Air Force Base. The emphasis of the testing is in the angle-of-attack range between 30 deg. and 70 deg. Longitudinal gross-acquisition handling qualities results show borderline Level 1/Level 2 performance. Lateral gross-acquisition testing results in Level 1/Level 2 ratings below 45 deg. angle of attack, degrading into Level 3 as angle of attack increases. The fine tracking performance in both longitudinal and lateral axes also receives Level 1 ratings near 30 deg. angle of attack, with the ratings tending towards Level 3 at angles of attack greater than 50 deg. These ratings do not match the expectations from the extensive close-in combat testing where the X-31A aircraft demonstrated fair to good handling qualities maneuvering for high angles of attack. This paper presents the results of the high-angle-of-attack handling qualities flight testing of the X-31A aircraft. Discussion of the preparation for the maneuvers, the pilot ratings, and selected pilot comments are included. Evaluation of the results is made in conjunction with existing Neal Smith, bandwidth, Smith-Geddes, and military specifications.

INVESTIGATION OF BUFFET LOAD ALLEVIATION ON A SCALED F-15 TWIN TAIL MODEL

Huttsell, L. J., Air Force Research Lab., USA; Tinapple, J. A., Air Force Research Lab., USA; Weyer, R. M., Aeronautical Systems Div., USA; Mar. 1998; 8p; In English; See also 19980202469; Original contains color illustrations; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

One of the common problems on twin tail fighters operating at high angles of attack is buffet. The Air Force Research Laboratory Unsteady Aerodynamics Integrated Product Team (IPT) performed an experimental buffet investigation on a scaled F-15 model. The model was tested in the Subsonic Aerodynamic Research Laboratory (SARL) located at Wright Patterson AFB, Ohio. Phase I of this program characterized the buffet characteristics and investigated tangential blowing as a means of buffet suppression. Phase II will investigate the use of piezoelectric actuators on the flexible tail to suppress the structural response due to buffet. A numerical simulation of the rigid model was performed for a Mach number of 0.2, 24 degrees angle of attack, and 4 degrees of sideslip using an unstructured CFD (Computational Fluid Dynamics) code. A second computation was performed to evaluate engine mass flow effects. This paper will present the results of the buffet tests, the computational effort, and a comparison of the computational and test results.

Flutter analysis requires the linking of structural deformation modeling with unsteady fluid dynamics; at British Aerospace, Aerospace Military Aircraft and Aerostructures (MA&A) a series of computational methods are used to model the various aspects of flutter to provide clearance data for aircraft. The various methodologies will be briefly described and the manner in which the parts of the

process interface outlined. Future aircraft require the tools to be capable of modelling complex configurations including novel planforms and aircraft with stores; these must also include the difficult transonic flow regime. The requirements of the unsteady methods needed to provide this capability and the manner in which they must be inserted into the existing process will be discussed. Initial results obtained using an unsteady Multiblock Euler method will be presented and the development of this method within the overall process will be detailed. These results will be used to illustrate the ways that sophisticated unsteady CFD methods must be developed, in terms of interface with structural components of the process, to meet project requirements for complex configurations. The post-processing requirements will also be presented.

This paper presents an overview on the AutoPilot design philosophy for a medium class, jet powered Unmanned Tactical Air Vehicle (U.T.A.V.) and the development of its Rig + Advanced Integrated Data Acquisition & Simulation System (Rig + AIDASS). After a short description of the Mirach 150 U.T.A.V. system, the synthesis methodology of the primary control laws for the steering and navigational modes are presented (Autopilot and Flight Management System). The process aims at verifying accordance between requirements and performances of the global system (Autopilot+Airframe). The performances of the system are shown: dynamic responses in front of altitude, groundspeed and heading demands and their maintenance in presence of atmospheric turbulence (MIL-F-8785/C). The study is developed in FORTRAN 77 language.

AUTONOMOUS NAVIGATION AND CONTROL FUNCTIONS OF THE CL-327 VTOL UAV

Pelletier, M., Bombardier, Inc., Canada; Sakamoto, A., Bombardier, Inc., Canada; Tessier, C., Bombardier, Inc., Canada; Saintonge, G., Bombardier, Inc., Canada; Jul. 1998; 10p; In English; See also 19990007836; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The CL-327 vertical take-off and landing (VTOL) unmanned air vehicle has a payload carrying capability of 100 kg and an on-station endurance of 4.75 hours at 100 km (based on 50 kg payload). Although similar to that of the CL-227, the pitch, roll, yaw and height autopilots have been modified and improved to account for the capabilities and dynamics of the CL-327. The advanced guidance, navigation and control functions include GPS/DGPS-aided flight, waypoint guidance, automatic (vertical) take-off and landing as well as autonomous flight without the intervention from the surface element. Because of these and other advanced features, the CL-327 is the world's most advanced VTOL UAV in production today.

RECONFIGURABLE FLIGHT CONTROL AT WRIGHT LABORATORY

Chandler, P. R., Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 44-47; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

Various government departments, including USAF Wright Laboratory, Naval Air Development Center, NASA, and ARPA are sponsoring the development of reconfigurable flight control systems. The reconfigurable system detects and compensates for in-flight failures and damage to maximize handling qualities and performance. Considerable success has been achieved to date. Some concepts have had limited flight tests, numerous piloted simulations have been performed on a range of aircraft, and lower risk portions of the technology have been transitioned to production A/C. The full benefit of reconfigurable flight control is just now being uncovered. Reconfigurable control is a subset of nonlinear or adaptive control. Compensating for large discrete events pays handsome benefits in survivability, fault tolerance, and safety of flight. Expansion of limited reconfiguration to a more fully adaptive approach pays even greater dividends. Such an approach will lead to faster development, reduced development costs, significantly less simulator tuning, a high degree of robustness to modeling errors and changes, and easy extensibility to new configurations and models. The technologies key to achieving these benefits are real-time parameter Identification (ID), on-line control design, control allocation, and command limiting. Work to date has concentrated on Failure Detection, Isolation, and estimation (FDIE), and control power redistribution. These techniques generally involve extensive off-line development and are heavily model dependent. Due to the effort involved, the reconfiguration capability is limited. A full ID and on-line design approach is highly adaptive. However, the technology is not yet available to field a fully adaptive flight control system today with acceptable risk. In particular, the ID must be fast and accurate, identifying critical control and stability derivatives. The on-line control design must be highly nonlinear and accommodate a full range of hard limits, as well as be computable on-line. In addition, stability and robustness analysis of an adaptive system must be made to ensure the system can be flight certified. In the following sections, only the efforts sponsored at WL will be discussed.

FACILITIES USED FOR PLASTIC MEDIA BLASTING

Foster, Terry, Esquimalt Defence Research Detachment, Canada; AGARD, Environmentally Safe and Effective Processes for Paint Removal; Apr 1, 1995, 4 p; In English; See also 19950025744; Copyright; Avail: CASI; A01, Hardcopy; A01, Microfiche

The equipment used for plastic media blasting (PMB) is generally independent of the media and is similar to equipment used in traditional abrasive blasting. PMB equipment is usually modified to enable the close control of the media flow and the operation at low pressures (30 - 40 psi). Because of the delicate nature of some of the stripping procedures, the nozzles used for PMB have been redesigned to improve cleaning rates, give an even distribution of particles and reduce the variation in particle velocity across the blast stream. This results in a more equal distribution of particles and impact energies at the substrate. There are three types of blast facilities available: blast cabinets for small components; blast booths which will accommodate larger components but may be used for purposes other than blasting, and blast rooms which are designed for complete vehicles or aircraft and are generally not used for other purposes.

The equipment of a turbomachinery test rig is at once critical and the same time expensive as soon as that unsteady measurements are placed in rotating parts of the machine. A predicting numerical simulation can then provide to the research worker useful information concerning the number of pressure sensors and their locations. Then, the challenge consists of predicting 3D unsteady aspect of the flow in a turbine, by using a flow computation which take into account viscous effects due to boundary layers, wakes and rotor blade tip clearance. Such computation in a whole stage would require a great deal of computer memory and time. At the present time, this is not possible and only the computation in a reduced stage (one or two blades of each row) can be considered. This computation induces some approximations in the description of the unsteady flow phenomena. The objectives of this study are the following: - the validation of the 3D approach (in a reduced stage) with respect to the unsteady phenomena, by means of 2D calculations for which the calculated blade number ratio is very closed to the actual blade number ratio; - setting out the computations results of unsteady 3D viscous flow in a turbine stage; - showing how these results can help to the choice of the pressure sensors. This study is the first step of the code validation in the field of 3D viscous unsteady flows in turbomachinery.

Effective Flight Simulation is an important capability for NATO nations, and it will become even more important in the face of reductions in defence budgets. This symposium reviewed the state of the art in flight simulation, in order to identify weaknesses where additional research and development are needed. Presentations dealt with simulation used for engineering and for training, both on the ground and in-flight. Session topics were: Visual and Motion Cueing and Requirements; Advances in Modelling; Simulation in Design and Development

- Rotorcraft; Simulation in Design and Development - Fixed Wing and Systems; Simulation in Training; In-Flight Simulation; and Future Applications.

HISTORICAL REVIEW OF PILOTED SIMULATION AT NASA AMES Anderson, Seth B., NASA Ames Research Center, USA; Apr. 1996; 14p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper traces the conception and development of in-flight and ground based simulators at NASA Ames Research Center, starting in 1947 and continuing to the early 1990's. Problems with their development and operation and how limitations were handled are recounted. Advances needed in simulator equipment to improve performance and fidelity to gain pilot acceptance are discussed. The uses of these simulators in various aircraft research and development programs and their importance to aircraft design and flight testing are reviewed. Challenges remaining include a better understanding of the tradeoff between motion cues and visual cues, the importance of simulation sophistication when examining aircraft with marginal handling qualities characteristics, and the continuing need for upgrading simulation technology as more complex problems are encountered. Additional research is needed to understand the human behavior aspect in the pilot/simulator system.

ACHIEVING HIGH-FIDELITY MOTION CUES IN FLIGHT SIMULATION

Advani, S. K., Technische Univ., Netherlands; Mulder, J. A., Technische Univ., Netherlands; Apr. 1996; 12p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The simulation of high-bandwidth manual flight control tasks dictate the use of simulator motion systems for the reproduction of motion cues on the vestibular and neuromuscular-mechanical arm manipulator system. The reproduction of these cues, with particular emphasis on the lowest possible time delay, is necessary in human perception research, experimental flight control system development studies, as well as in routine flight training. Perfect reproduction of motion cues with ground-based flight simulators is principally impossible due to the kinematic limitations inherent to the motion system. Washout filters minimize these effects. The dynamic characteristics of the motion system however lead to two types of control errors: short-term, due to finite oil stiffness and line dynamics, as well as limited control valve bandwidth, and long-term, due to complexity of the non-linear motion system dynamics, making compensation of unwanted parasitic errors difficult. This paper will review techniques which increase the performance of six-degrees-of-freedom hydraulic motion systems for flight simulators. Application of pressure-feedback actuator control increases the robustness of the motion system dynamics, hence decreasing the short-term errors. The long-term control errors are addressed by a (separate) robust, multi-variable motion system controller which provides control signals to the platform with knowledge of the system state and its inherent properties. The total mass and the vertical location of the center of gravity of the platform influence the time delay (phase lag) and fidelity of the motion system. These properties also limit any such improvements due to design changes in software or hydraulic hardware. As a result of these studies, a fundamentally unique light-weight motion platform design is proposed, making extensive use of advanced composite materials. This is called the SIMONA Research Simulator. With the improvements made to motion cue quality, fundamental research into human

perception processes in human perception research, and experimental flight control system development work, will not be influenced by parasitic motions.

SHIP AIRWAKES: A NEW GENERIC MODEL FOR PILOTED SIMULATION

Woodfield, Alan A., Woodfield Aviation Research, UK; Tomlinson, B. N., Defence Research Agency, UK; Apr. 1996; 18p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The disturbed airwake in the lee of the superstructure of ships with an aft flight deck causes significant control problems for helicopters operating during strong winds. Providing adequate data to describe these airwakes for use in night simulators has been a difficult task from either wind tunnel tests or theoretical airflow estimates. In this report an empirical mathematical model is developed based on the main types of airflow pattern present in airwakes. The model uses a single set of modelling parameters to produce airwake data for any shape of ship with an aft flight deck and for any wind direction. Assessment of the model in a piloted flight simulator has been very favorable with the main criticism being the absence of turbulence which is available in the model but could not be used because of difficulties in simulating helicopter responses at that time. Comparison of airwake estimates with a set of boundary layer wind tunnel results shows good agreement in the complex flow with the wind from starboard at 30 deg. and suggests some areas where adjustments to the model could improve the comparison for other wind directions. The model has highlighted several interesting features of airwakes, including probable improvements in airwakes if hangar tops can have porous net fences around the edges, the effects of gradients in vertical airflow velocities on control of a helicopter's height, and the need to include response to flow gradients in helicopter aerodynamic models for simulation of operations in airwakes. It is recommended that the airwake model should be validated against full scale and wind tunnel data on other shapes of ship, and, after any necessary adjustments to the model, it should be used for a trial installation on a suitable existing helicopter training flight simulator, prior to introduction into general use for R & D in helicopter/ship research programs and for helicopter training simulators.

A DYNAMIC CHALLENGE: HELICOPTER/SHIP INTERFACE SIMULATION: DEVELOPMENT, INTEGRATION AND APPLICATION

Tate, S. J., Defence Research Agency, UK; Apr. 1996; 16p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Piloted simulation has a potentially major role to play in training, test and evaluation and research in support of the helicopter/ship dynamic interface. The combination of visual/motion cueing and vehicle/environment modeling problems makes the helicopter/ship dynamic interface one of the most challenging in the simulation of aerospace vehicles. The exacting fidelity requirements of this application have hindered the use of simulation in this area until recently. This paper reviews the major fidelity issues of helicopter/ship interface simulation and describes some of the findings of a survey carried out of current simulators to attempt to identify areas that require improvement. The cost and operational benefits of the use of high fidelity piloted simulation in this field are outlined. Current Defense Research Agency (DRA) research work directed at improving models of the natural environment is described, as well as the thrust that future work will take. The uses of the high fidelity helicopter/ship dynamic interface simulation of the DRA Advanced Flight Simulator (AFS) in support of other research packages is described. This work covers the establish-

ment of handling qualities criteria for maritime helicopters and the use of simulation to develop improved pilot visual cues for deck operations. Use of simulations has allowed rapid development at relatively low cost and at much reduced risk.

USE OF SIMULATION FOR DESIGN OF THE RAFALE NAVIGATION AND ARMAMENT SYSTEM UTILISATION DE LA SIMULATION POUR LA CONCEPTION DU SNA DU RAFALE

Goussault, R., Dassault Aviation, France; Leclerc, M., Centre d'Essais en Vol, France; Apr. 1996; 8p; In French; See also 19970000594; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In this presentation conducted jointly by Dassault Aviation and the Flight Test Center (FTC), we first indicate important innovations introduced into the design of the Navigation and Armament System of Rafale Airplane and in particular the fundamental role of simulation. We subsequently show the synergy that exists between Dassault Aviation and the Flight Test Center and definition of the needs for this simulation, in the choice of models and equipment that comprise it and in its use by the industrial architect of the state. A few comments are necessary before entering into the heart of the matter: in the Rafale program, Dassault Aviation is the industrial architect of the Navigation and Armament System; the Flight Test Center is, within the General Administration for Armament, the expert state organization for flight tests as well as applications of aviation equipment and military on-board systems; and simulation here designates pilot simulation.

ARC SEGMENT ATTITUDE REFERENCE (ASAR): SIMULATOR APPLICATION DURING THE DEVELOPMENT PROCESS OF A NEW ATTITUDE REFERENCE SYMBOLOGY

Fuchs, W., Daimler-Benz Aerospace A.G., Germany; Fischer, G., Daimler-Benz Aerospace A.G., Germany; Flight Simulation: Where are the Challenges?; Apr. 1996; 6p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Pilots of modern fighter aircraft with high pitch and extremely high roll rates complain about fast moving and twisting pitch ladders on the head-up display (HUD) and the necessity to virtually concentrate their entire attention on the attitude references in order to maintain orientation in space when performing aggressive three-dimensional maneuvers. For this reason we were considering a more stationary flight attitude symbology to allow for attitude awareness, which requires less attention and concentration. The result was the introduction of the Arc Segment Attitude Reference (ASAR) Symbology. After a number of

09 RESEARCH AND SUPPORT FACILITIES (AIR)

alternating simulator trials and flight tests for further development and refinement of the symbology, a final version was agreed and already implemented in experimental programs.

ISSUES IN THE FLIGHT CLEARANCE OF VEHICLE MANAGEMENT SYSTEMS

Diston, D. J., British Aerospace Defence Ltd., UK; Weller, B. R. C., British Aerospace Defence Ltd., UK; Apr. 1996; 14p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The adoption of highly-integrated and complex aircraft systems will facilitate the development of optimum strategies for vehicle management. This will provide benefits in functional performance and operational effectiveness. The drive towards standardization implies the adoption of some form of modular avionic architecture, thereby adding the benefits of improved logistics. In this paper, it is argued that these developments force a fundamental review of existing approaches to flight clearance. A number of challenges are proposed in the areas of Operating Systems, Analytical Control Theory and 'Virtual Rig' Simulation. In conclusion, the paper anticipates the evolution of a 'modular' procedure which might provide a legal basis for the certification of aircraft systems.

The Dutch National Aerospace Laboratory NLR has developed during the last three years an advanced Full Mission Simulation capability for fast jet fixed wing and rotary wing aircraft. This Full Mission simulator, named the National Simulation Facility NSF, is created for research in training methodologies, investigation of simulation and simulator requirements for specific training tasks and to support industrial development of cockpit and aircraft systems. The current capability of the simulator focuses on the F-16 Mid-Life Update configuration, but will be extended to accommodate manned helicopter simulation later this year. The latter will be directed towards the recently (by the Dutch Air Mobile Brigade) procured Boeing CH-47D Chinook medium-heavy transport helicopter, and the McDonnell Douglas AH-64D Apache attack helicopter. This paper will address the various technical aspects of the National Simulation Facility.

The Studies and Simulation Section of the Flight Test Center (Ministry of Defense) is participating closely in development of navigation and armament systems for all aircraft carrier programs (Rafale, Tigre, Mirage 2000, ...). The simulation tests of these navigation and armament systems require implementation of targets or teams that would comprise the tactical environment of the pilot. But as a function

of the state of advancement of the investigations, the need varies from an automatic tactical environment to implementation of a team or of piloted targets for a greater level of realism.

ASRA: A NEW TOOL FOR IN-FLIGHT SIMULATION. CURRENT STATUS AND ACTUATION STUDIES

Morgan, J. Murray, National Research Council of Canada, Canada; Baillie, Stewart W., National Research Council of Canada, Canada; Flight Simulation: Where are the Challenges?; Apr. 1996; 8p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The Flight Research Laboratory (FRL) of the Institute for Aerospace Research (LXR) is in the process of developing an Advanced Systems Research Aircraft (ASRA) based on a Bell 412HP helicopter. This paper describes the current status of this facility, and discusses the approach being taken towards fly-by-wire actuation in this high control power host vehicle. The primary problem faced in designing a research fly-by-wire (FBW) actuation system for this aircraft is that of maintaining an adequate level of flight safety throughout the entire flight envelope, while limiting its simulation capabilities as little as possible, this is discussed. A scheme for compound actuation of the 'critical' axes is introduced. Initial off-line simulations of various failure modes are described and the results presented. The purpose of this paper is to present to the community a proposed approach to this problem and to describe some initial studies in support of the design concept used.

This paper gives an overview of DLR's latest flight experiments, both with the fixed-wing in-flight simulator ATTAS and the helicopter in-flight simulator ATHeS. After a detailed description of both testbeds and the corresponding ground based simulators, flight test results are presented. These include experiments on in-flight simulation, rate saturation, reconfiguration, flight control laws, handling qualities, and vision based hovering. The paper concludes with a discussion on certain aspects of simulation fidelity.

The need to combine simulators or simulations grows each day, and the diversity of these simulations is very great. Past experiments have demonstrated that it is nearly impossible to interconnect pre-existing simulations when necessary for this purpose to use common methods and structures that are imposed for all simulations. The availability of Interactive Distributed Simulations (SID) allows one to combine heterogeneous simulations without having to modify them in an important way. In addition, current simulators have certain partic-

ular features when one compares them to recent simulators. They are often limited in memory, calculation power, and only rarely have means to connect to communication networks.

HIGH FIDELITY, MOBILE, NET WORKABLE TRAINERS: THE TRAINERS OF THE FUTURE?

Miller, Chad C., Naval Air Warfare Center, USA; Perdue, David, Naval Air Warfare Center, USA; Davis, Scott, Naval Air Warfare Center, USA; Apr. 1996; 8p; In English; See also 19970000594; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The U.S. Naval Air Warfare Center Aircraft Division Patuxent River personnel recently completed a high fidelity, low cost mobile prototype AH-1W Aircrew Procedures Trainer for the USA Marine Corps at Camp Pendleton, California. The use of recent technological breakthroughs in both super-micro computers and visual display technologies made this program possible. These breakthroughs pave the way for future OFT/APT developments. The AH-1W APT project demonstrated the application of evolving simulation technology in four areas. First, that new technologies reduce the physical size of room required to support computational requirements of WSTs. Second, newer technologically advanced COTS computers can be used in a rugged environment without any special expensive considerations. Third, existing full-size training systems could be supplemented or replaced by such small, mobile devices such as the AH-1W high fidelity trainer prototype constructed at NAWC AD. Fourth, fixed wing tactical aircraft training systems that do not require motion cueing devices are particularly attractive for this application.

This survey paper reviews current practices in simulation technology with emphasis on aircraft development and testing, followed by a discussion of present and future applications of distributed simulation and synthetic environments. The aviation community has used a wide variety of simulation tools for over 35 years. The benefits of current generation standalone simulation tools, including system integration laboratories, are well understood. Distributed simulation is beginning to be used to support training and requirements definition; test applications are also beginning to be explored. Advanced distributed simulation provides an unprecedented opportunity to explore new concepts as well as improve the efficiency of test and training activities. With the rapid increases in information processing technology, synthetic environments will be used increasingly to support test and training, both in standalone and interactive distributed modes. There are numerous challenges in developing and applying these technologies; including simulation fidelity and scalability, verification and validation. There is also a need to decrease simulation costs. The emergence of distributed simulation has been the catalyst for increased interaction between the simulation world and test and training systems. Next generation range and platform instrumentation architectures will be designed to facilitate interaction between live players and simulated entities.

References to 'Defence Synthetic Environments' are becoming more common with the passage of time. At present, the term means different things to different people driven largely by their viewpoint within the defence business. Indeed, to confine the concept to the defence business is already narrowing the vision according to some. There are envisaged opportunities for applying similar techniques in commerce, medicine, transport and so on. In fact any large system is a potential candidate. The defence business was, however, probably the first to adopt the name and to start demonstrating what it means. In the UK, joint government and industry groups have been established to steer national activities for SE's. A number of early demonstrators are underway. In the USA, regular networking demonstrations illustrate how this particular component of SE is maturing. The general impression is one of commitment to SE as a long term goal. The intention of this paper is to give a view of the extent of Synthetic Environments (SE) and to discuss how it may be put together and used to help the defence business. In doing this the role of Flight Simulation within SE is highlighted along with the challenges which it faces. The need for improvements throughout the defence business hardly needs justification here. Pressures created by falling defence budgets, uncertain threats, shorter development times and heavy competition all point to the need for process improvements right across the board. To embrace the opportunities offered by SE requires changes in all the parties involved including the customer. The resulting increase in effectiveness and level of concurrency between all the stakeholders should be a worthwhile payback.

Results of the first experimental evaluation of the Advanced Spatial Disorientation Demonstrator (ASDD) installed at Brooks AFB, TX are described. The ASDD was evaluated by a mix of experienced pilots and novices. Spatial Disorientation (SD) training profiles were programmed into the device in an attempt to induce Type 1 (unrecognized) and Type 2 (recognized) SD. Reliable generation of SD illusions and visual/vestibular sensory conflicts on the ground, in a safe environment, can in principle provide training to aircrew to aid in recognizing and coping with SD in flight, and also can be used as an environment to design instrument displays. To that end, the ASDD components, SD profiles, and training potential were evaluated.

The use of motion based training devices permeates all of Aerospace Physiology training and continues to grow in sophistication. Motion based training devices present the opportunity for truly interactive training. However, for such devices to be completely effective, they must possess the qualities of low acquisition and operating cost, multiple task training capability, flexibility of use, and high fidelity, and they must be interactive. Future development of motion based training devices for physiological training should be a start-to-finish joint effort between customer/user groups, research centers of excellence and industry as a cooperating triad.

The search for ground-based devices that can generate realistic motion and forces of an aircraft in flight is ongoing. However, with the maturing of several technologies, mostly in the computer and visual arenas, the Advanced Spatial Disorientation Demonstrator (ASDD) has surfaced as the prime United States Air Force (USAF) candidate. It combines these new technologies to generate repeatable and sustainable flight-like forces with unsurpassed fidelity. The device, though still in its infancy, has proven that realistic spatial disorientation (SD) illusions can be generated in a safe, ground-based environment. This program overview highlights the ASDD's capabilities, which will have a dramatic impact on the way pilots will receive SD familiarization training for the next decade.

German Air Force acquired the 'Flight Orientation Trainer (FOT)' and installed it in the facilities of the German Air Force Institute of Aviation Medicine (GAF IAM) in Fuerstenfeldbruck to improve its training efforts in aviation physiology and especially in spatial disorientation. In 1994 a troop trial was conducted to have the FOT tested and evaluated by experienced pilots of the German Armed Forces. Results of the troop trial are described and the best timing for training in the FOT is discussed. The evaluation and validation of the FOT requires calibration and counter-measure equipment to cover various aspects of spatial orientation, situation awareness and motion sickness. The relevance of pilot's ability to react under changing orientation can be shown in a orthostatic stress test on tilt-table. An individual susceptibility for syncopal reaction can lead to loss of awareness and motion sickness.

The subject of low altitude flying training has received increased attention in recent years for political and technical reasons, including cost, environmental impact and the expanding training requirements of modern airborne weapon systems. Conducting low-level flying training 'live' is becoming less and less acceptable in many NATO nations, while the threat continues to demand even lower altitudes at higher speeds. Restrictions on low flying training exist in many countries, and include reduced low flying time, speed restrictions, and altitudes restricted to no lower than 1000 ft. Following the AASC studies on 'Low Level Flight Training' and 'Reduction of the Environmental Impact of Operational Flying Training', Working Group 20 was established by the AGARD Flight Mechanics Panel (now the Flight Vehicle Integration Panel) to build on their conclusions and to examine the current capability and future potential of simulation technology in low altitude high speed mission training and rehearsal. It held its first

meeting in October 1991. In conducting its review, the Working Group examined some relevant mission simulators in several NATO countries: the UK Harrier GR Mk5/7 mission simulator, the German Tornado Low-Level Test Bed simulator, and the US Apache helicopter Combat Mission Simulator.

Report No.(s): AGARD-R-812; ISBN 92-836-1047-4; Copyright Waived; Avail: CASI; A13, Hardcopy; A03, Microfiche

The development and use of cryogenic wind tunnels represents a major advance in aerodynamics testing. One advantage of cryogenic tunnels is their ability to achieve full-scale values of Reynolds number in tunnels of moderate size at reasonable operating pressures. Another important advantage is the ability to independently vary temperature, pressure and speed, which lets one separate the effects of Reynolds number, aeroelasticity and Mach number. This series of lectures, supported by the AGARD Fluid Dynamics Panel and the von Karman Institute, incorporated a brief review of the development and early uses of cryogenic tunnels, and reports on current operational cryogenic facilities. It then covered the theory and advantages of cryogenic wind tunnels, as well as the special considerations required in their design, construction, and use. Subjects included cryogenic systems, thermal insulation, facility and model design and construction, strain-gage balances, pressure instrumentation, flow visualization, data accuracy, safety, and productivity.

INTRODUCTION TO CRYOGENIC WIND TUNNELS

Goodyer, M. J., Southampton Univ., UK; Special Course on Advances in Cryogenic Wind Tunnel Technology; Feb. 1997; 14p; In English; See also 19970016374; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The situation which existed in the era which spawned the cryogenic wind tunnel, the early 1970's, is first explained. The background includes the strong desire felt at that stage to raise Reynolds number in transonic testing, together with the response in the form of the expensive solutions then under consideration. Some paper studies describing the benefits of changing test temperature did exist, mostly older and obscure, but had been ignored up to this time. This situation coincided with the contemporary state of maturity of cryogenic engineering. The cryogenic wind tunnel evolved in this environment as the way to increase Reynolds number while avoiding undue increase of wind tunnel size or operating pressure. The paper describes the theoretical principles, showing the way in which it achieves its aim. Some cryogenic wind tunnel practice is included, also a description of beneficial feature additional to achieving high test Reynolds numbers. These are a rather important reduction of motor power in the case of fan-driven tunnels and the ability for the first time in wind tunnel testing to isolate the separate effects of change in Reynolds number, Mach number and dynamic pressure. Finally there is an outline of the way in which cryogenic operation affects some representative types of tunnel.

The basic concepts of yield, plastic deformation, toughness and crack propagation are discussed in the context of those alloys likely to be used in cryogenic wind tunnels. The mechanical and physical properties of the major alloys used for model construction are discussed and summarized. Dimensional instability in 15-5PH and 17-4PH stainless steels makes them unsuitable for use, but 304L, A286, Nitronic 40 and PH13-8Mo have been used successfully. 200 grade 18 nickel maraging steel has been extensively used for constructing models and stings, but for large diameter forged bars the Charpy impact energy, Cv, at 77K falls well below the required value of 34 J. An empirical relationship between bar diameter and C(sub v) at 77K is demonstrated for samples cut in the AR, RR and RA orientations, the orientation effect being most marked between diameters of 150 and 400 mm. The use of 250 grade 18 Ni maraging steel and beryllium copper for balances is also considered. Fabrication techniques are discussed with particular reference to the dimensional changes induced by different machining operations and the implications for the fabrication of high-accuracy components. Non-conventional machining methods and various joining techniques are also discussed. The availability of information in a form suitable for use in model design and stress calculations is discussed in the light of the recent publication of the ETW Materials Guide and the data compilations in its appendices.

This lecture presents current information on cryogenic model design requirements, developmental model design studies, design and fabrication experience, recent surface finish and pressure orifice studies, and current practices for filler materials and fastener applications. In addition, results of advanced model support system studies are presented along with composite model designs for cryogenic application, and information relating to cost factors for cryogenic models versus conventional models. Finally, some future development needs are suggested for cryogenic model systems.

FORCE TESTING WITH INTERNAL STRAIN GAGE BALANCES

Hufnagel, Klaus, Technische Univ., Germany; Ewald, Bernd, Technische Univ., Germany; Feb. 1997; 18p; In English; See also 19970016374; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The ever rising accuracy requirements in wind tunnel testing for airplane development enforce continuous improvement of force testing technology. The introduction of the cryogenic tunnel is an addi-

tional challenge for the force balance since now the balance accuracy is requested over an operational temperature range of 200 Kelvin. More than 15 years ago several teams in the world therefore started with investigations in the area of internal balances for cryogenic wind tunnels. In Germany in 1979 the 'Cryogenic Balance Program' was started by the German Ministry for Research and Technology with the target to develop internal balances and calibration technique for the planned cryogenic wind tunnels KKK and ETW. In the past 17 years of research all aspects of force testing technology have been dealt with and developed to new standards by the Technical University of Darmstadt together with Deutsche Aerospace Airbus GmbH, Bremen. Within this period 8 balances for cryogenic wind tunnels were built. Basic research on the aspects of metallic spring materials resulted in new understandings about material selection and material treatment for optimum results. Principle balance design optimizations are done with finite element analysis. For the routine balance design an interactive computer program was created. The very successful technique of the Electron Beam Welded Balance was developed. The balance structure is fabricated from parts, which are welded together by electron beam welding. This technique makes it possible to build balances with a complex inner structure to minimize the interferences. For cryogenic balances the main problems are zero shift and sensitivity shift over the large temperature range and false signals especially in the axial force element due to temperature gradients. The problems were overcome by a very careful strain gage matching process by use of special gages by application of numerical corrections and by a special design of the axial force system with tandem measuring elements in the flexure groups.

This paper summarizes a number of aerodynamic phenomena mainly related to cryogenic pressurized testing. The goal of the analysis effort has been to address aerodynamic difficulties associated with the severe environment of this cryogenic wind tunnel. The first part describes some of the various flow parameters important to respect the achievement of the best similarity between an aircraft in flight and the model in the wind tunnel. The second part covers the different effects of these factors from simple 2D cases to complex 3D flows: effects of the Reynolds number on laminar and turbulent flows, boundary layer transition, influence of non adiabatic model wall. Theoretical and experimental points of view are presented and illustrated with practical examples. Efforts to obtain reliable and accurate results have been done in the past and need to be continued to provide the scientists and manufacturers which results leading to a better optimization and prediction of the aircraft performances.

The Cryogenic Ludwig-Tube of DLR at Gottingen (KRG) is a blow-down wind tunnel designed for high Reynolds number research in transonic flow. Temperatures down to 100 K and stagnation pressures up to 1 MPa are applied to achieve Reynolds numbers of up to 60×10^6 (2-D) based on a model chord of 150 mm. In 1994, a new test section with 2-D adaptive walls was installed after the performance of the KRG had been evaluated with a relatively simple slotted wall test section. This paper gives an overview over the Ludwig-Tube concept and describes the design and operation of the facility as well as the main components with special emphasis on the new 2-D adaptive wall test section and the adaptation method. Two techniques to determine transition under cryogenic conditions have been tested and

T2 TRANSONIC CRYOGENIC WIND TUNNEL AT TOULOUSE

Seraudie, Alain, Centre d'Etudes et de Recherches, France; Archambaud, Jean Pierre, Centre d'Etudes et de Recherches, France; Feb. 1997; 14p; In English; See also 19970016374; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

T2 is an induction driven wind tunnel in which Reynolds number variations are obtained by increasing the total pressure ($P_{\text{sub } t}$) = 1,4 to 3 bar) and reducing the total temperature ($T_{\text{sub } t}$) = 300 to 110 K). The flow is driven by an injection of dry air at ambient temperature and cooled by another injection of liquid nitrogen. This paper presents the evolution of T2 wind tunnel, mainly in cryogenic condition since 1981, and the aerodynamic cryogenic developments we performed around the wind tunnel activity. Firstly it gives the wind tunnel main characteristics, it describes the flow control system, and the hollow model technique developed for cryogenic runs. The flow quality measurements are presented, with pressure, temperature, and mass flow fluctuation levels. Moisture contamination is a great problem for flow quality, and we present some solutions to perform good tests on laminar models at high Reynolds numbers. Finally this paper presents some typical results obtained in cryogenic condition: velocity measurements with a laser Doppler anemometer, transition qualification at variable Reynolds number and buffeting investigation with unsteady measurements.

THE CONCEPT OF THE KRYO-KANAL-KOLN (KKK) OPERATIONAL EXPERIENCE, FLOW QUALITY, MODEL HANDLING AND HALF MODEL TESTING TECHNIQUE

Viehweger, G., Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Germany; Special Course on Advances in Cryogenic Wind Tunnel Technology; Feb. 1997; 10p; In English; See also 19970016374; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The aerodynamic calibration of the KKK at ambient and cryogenic temperatures was completed in 1989. In parallel the control system of the tunnel, which is constructed in a modular basis, was modified and improved to save liquid nitrogen consumption. During this time operating problems in the circuit and in the subsystems resulting from the cryogenic mode of operation were identified and solved. Basic tests were performed to understand the physics of the desorption of moisture from the internal insulation into the circuit which resulted in a special purging procedure before cryogenic operation. The aerodynamic tests demonstrated the high flow quality in the test section in the whole operation range. This paper will give a review on the experimental experience and describes the test equipment of the tunnel.

Model dynamics is a continuing problem when testing in high Reynolds number, high pressure, cryogenic wind tunnels. This lecture describes model and model support vibration problems that have been encountered in the National Transonic Facility located at the NASA Langley Research Center. Test experience and studies related to identification of excitation sources, attenuation of model vibrations, and changes in structural damping at cryogenic temperatures are presented. Results of a successful buffet test conducted in the National Transonic Facility are discussed along with studies of the effects of model vibration on inertial wind-tunnel model attitude measurement devices. Finally, online model systems dynamics monitoring systems currently being used in the National Transonic Facility are described.

Throughout the project stages, from the planning and design phases through to the present initial operations phase, it has always been recognized that technical excellence and productivity were fundamental to the success of ETW. In a fiercely competitive market technical excellence must be consistent with state of the art transonic testing especially at high Reynolds numbers. Test techniques have therefore been developed to achieve the high productivity levels required by industrial users for efficient testing. This paper reviews the major features of the test techniques developed which aim at achieving a high technical quality of testing and a high productivity. Special attention has been paid to ensure that the design for high productivity, has not compromised the technical quality of the final data output.

The ETW is a closed circuit, continuous flow transonic windtunnel operating with gaseous nitrogen over a temperature range of 90 K to 313 K and up to 4.5 bar absolute total pressure. For correct simulation of real flight conditions of an aircraft in a windtunnel, the most advanced measurement techniques have to be applied. One important measuring tool is the 'Internal Strain Gauge Balance'. The Internal Balance (IB), dynamometric transducer, for a full span aircraft model is mounted between the model and the model support sting. These balances are required to measure, to the highest degree of accuracy, the aerodynamic loads acting on a model during windtunnel testing, whilst operating in the test section in conditions defined as above. To achieve high accuracies for model load measurements, the basic performance of the balances under all operating conditions and the precision of the balance calibration process prior to the test in the wind tunnel, are of fundamental importance. The aerodynamic loads acting on the model aerodynamic center during the test are represented by a vector force and a vector moment. These are both split on a reference axis system attached to the above mentioned center, into six

aerodynamic components; three forces and three moments. In order to give a comprehensive aerodynamic analysis of a model under wind, the measuring instrument Internal Balance must be able to measure each of these six degrees of freedom.

The first cryogenic tunnel was built at the NASA Langley Research Center in 1972. Since then, many cryogenic wind-tunnels have been built at aeronautical research centers around the world. In this lecture some of the more interesting and significant of these projects that have not been covered by other lecturers at this Special Course are described. In this lecture authors describe cryogenic wind-tunnel projects at research centers in four countries: China (Chinese Aeronautical Research and Development Center); England (College of Aeronautics at Cranfield, and Defence Research Agency - Bedford); Japan (National Aerospace Laboratory, University of Tsukuba, and National Defense Academy); and United States (Douglas Aircraft Co., University of Illinois at Urbana-Champaign, and NASA Langley).

Report No.(s): AGARD-CP-585; ISBN 92-836-0042-8; Copyright Waived; Avail: CASI; A19, Hardcopy; A04, Microfiche

The aim of this Symposium was to gather and review both current knowledge and ongoing research on the aerodynamic design and evaluation of ground test facilities, focusing primarily on wind tunnels, in order to provide to the designers of experimental facilities an opportunity to exchange information, ideas, and visions. Shrinking budgets for new facilities have led to fewer facilities being developed and longer development times, which have in turn led to less opportunity for advances in the state-of-the-art and for the retention of the experts needed for the design of good experimental facilities. The normal overriding user objectives, when conducting almost any kind of wind-tunnel test, are obtaining reliable and meaningful data in a timely and cost-effective manner. Principal requirements for obtaining reliable and meaningful data are an adequate Reynolds number, representative or

satisfactory tunnel flow quality, and the avoidance of tunnel wall and support system effects. Factors which are important in satisfying the timeliness and cost effectiveness requirements include minimizing the time required for model installation and configuration changes, utilization of efficient data gathering systems, and the ability to use rapid techniques to account for tunnel wall and support system interference effects. Since the aerodynamic design of wind-tunnel circuits has a fundamental first order effect on tunnel flow quality, tunnel wall and support interference effects, and on tunnel construction costs, the adequacy of the circuit design is of crucial importance in meeting the user's objectives. It should be noted that this was the first AGARD Symposium held in Russia, and that 50% of the papers were by Russian authors. Much information was shared by those who are involved in developing, operating, and utilizing experimental ground test facilities.

A team of young scholars, engineers and pilots possessing already a practical experience of researches in the area of aerohydrodynamics at the Computation and Research Bureau (CRB) established within the Moscow High Technical College (Moskovskoe Vyshee Tehnicheskoe Uchilishche MVTU) in 1916 formed the kernel of TsAGI headed by N.E. Zhukovskiy. The foundation for these researches was laid by a methodology created by N.E. Zhukovskiy and consisting in a continuous combination of fundamental, searched-for and applied researches with experimental investigations in the wind tunnels. This principle was preserved and developed through all stages of activities of TsAGI where the problems of creation of the experimental aerodynamic equipment and development of the scientifically grounded test methodology had always been of primary emphasis.

Requirements for obtaining reliable and meaningful data in most wind tunnel test situations are addressed from an aircraft industry user's perspective. Factors considered are Reynolds number requirements, tunnel flow quality requirements, and tunnel wall and support system effects. Factors which are important in satisfying timeliness and cost effectiveness requirements are also identified. Important flow quality imperfections which exist with less-than-perfect wind-tunnel circuit aerodynamic design are considered, together with a review of the existing knowledge base for assessing the likely/potential effects of variations in these imperfections on the resultant test data. The need to have a thorough knowledge of the important flow physics features which are controlling the aerodynamic, aeroacoustic, and/or propulsion characteristics of the vehicle or flow situation under investigation at the associated test conditions is stressed in order to adequately understand and identify wind-tunnel flow quality requirements and effects on data quality, accuracy, and adequacy. The importance of not limiting the identification of potential data errors and measurement uncertainties to just those which can be currently quantified with existing analytical and computational methods is also stressed, as is the importance of understanding the aerodynamic design and validation process in which the data is being used, and the risk involved in the particular design being investigated. Additional considerations

09 RESEARCH AND SUPPORT FACILITIES (AIR)

which need to be given attention when conducting some specialized types of tests (icing, semispan, open throat, etc.) are addressed. Examples of observed and easily-envisioned flow-quality variation effects on measured aerodynamic characteristics are presented. Lastly, prospects for improving tunnel flow quality through application of current advanced CFD capabilities are highlighted, as well as prospects for incorporating advanced test-section wall ventilation concepts to enable more reliable and cost effective high Reynolds number testing capabilities.

Since the sixties NLR was considering conceptional layouts and airline diagrams for the next generation low speed wind tunnels. This has resulted in the construction of a multi-purpose pilot facility in the early seventies. Based on the experiences gained from this facility, three major wind tunnels have been realized and are in full operation to great satisfaction of the operators and users: namely the DNW (1980) and LST (1983) facilities in the North East Polder in The Netherlands and the ILST (1987) near Jakarta in Indonesia. In this report the general design considerations in terms of aerodynamic and testing requirements are reviewed and are compared with the actual achievements. Also other operational aspects, such as logistics, acoustics, local constraints, and model supports are considered. From these aspects some lessons learned are concluded and recommendations made.

This paper describes the aerodynamic and structural design of two pressurised low-speed tunnels built in the 1970's to achieve a Reynolds number of 6×10^6 and, at the same time, to enable the effects of compressibility and scale to be studied independently in tests of aircraft models in take-off and landing configurations. Despite being designed to similar specifications and providing comparable levels of flow quality, productivity and customer confidentiality, the tunnels differ significantly in several important aspects of their design. The principal features of the two designs are reviewed and a few examples of the compressibility and scale effects that have emerged from the test programmes in each tunnel are presented.

SUBSONIC WIND TUNNEL WITH FLOW SPEED PULSATION

Ryabokon, M. P., Tsentrlni Aerogidrodinamicheskii Inst., Russia; Malyk, A. G., Tsentrlni Aerogidrodinamicheskii Inst., Russia; Jun. 1997; 8p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

A number of calculations and experiments within the program of developing a subsonic wind tunnel with flow speed pulsation in the test section were carried out at TsAGI. The wind tunnel was designed to perform aerodynamic tests of models in regularly fluctuating flows within the Mach number range up to 0.9 with the fluctuation amplitude up to 40% of the mean flow velocity and the frequency of pulsations up to 20 Hz. One of the possible concepts of developing a wind tunnel

with flow speed pulsation was used. Speed pulsation is generated using rotating elliptic shafts located parallel in one of the wind tunnel cross sections downstream of the test section. The air is injected into the wind tunnel from the atmosphere by means of an ejector. The results obtained were applied for designing a wind tunnel prototype with the 0.4 (W) x 0.7 (H) m test section. Special attention in developing the wind tunnel was given to the problem of obtaining the velocity pulse shape in the test section close to the sine curve. For this purpose special correcting devices were introduced in the wind tunnel structure. Investigation showed that shock waves can be generated in pulsing flow at transonic flow velocities. The upper velocities at which no shock waves are generated have been determined.

AERODYNAMIC DESIGN OF A CIVIL-AERONAUTICAL LOW SPEED LARGE WIND TUNNEL

Gibertini, G., Politecnico di Milano, Italy; Gasparini, L., Politecnico di Milano, Italy; Zasso, A., Politecnico di Milano, Italy; Jun. 1997; 10p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The new Civil-Aeronautical Low Speed Large Wind Tunnel is presented, which will be constructed in the near future at the Politecnico di Milano. This unconventional facility will allow for both civil environmental and aeronautical researches, respectively in a very large (14 x 4 m) low-speed test section and in a conventional high-speed test section (4 x 4 m). Based on the results of preliminary tests on a 1:9 scale model the design of some critical components was reviewed. This includes the numerical optimisation of the contraction ahead of the aeronautical test section, the inverse design of a new thick section for the corner vanes and an improved configuration of the bends upstream the civil-environmental test section. Tests performed to check the effectiveness of the proposed modifications, although showing that some work is still needed to fulfill the specified requirements, confirmed the feasibility of this very peculiar wind tunnel.

EXPERIMENTAL AND COMPUTATIONAL AERODYNAMICS APPLICATIONS FOR AN ICING WIND TUNNEL DESIGN

DeGregorio, F., Italian Aerospace Research Center, Italy; Esposito, B., Italian Aerospace Research Center, Italy; Mingione, G., Italian Aerospace Research Center, Italy; Vicini, A., Italian Aerospace Research Center, Italy; Jun. 1997; 10p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The Italian Center for Aerospace Research is committed to the design and construction of a new icing wind tunnel (IWT). The main feature of an icing wind tunnel with respect to a traditional aerodynamic one is to have a heat exchanger to cool the air flux, and a spray-bar, normally located in the settling chamber, to generate water droplets simulating the supercooled water droplets clouds that can be encountered in flight conditions. The IWT will have peculiar characteristics, such as flight altitude pressure and humidity control, and large droplet simulation (larger than those indicated in present FAA regulations). The need for these features has been identified in the preliminary design phase, and their impact on the design has thus been evaluated. In this paper a short description of the main characteristics of the CIRA IWT will be given, and some of the experimental and theoretical studies that have been carried out during the feasibility study will be illustrated.

There is a general understanding that aircraft design is a mature technology. All leading airframe manufacturers produce a high quality product, with a blend of sophisticated computational fluid dynamics programs and extensive wind tunnel tests. Prediction of flight characteristics and performance is usually made with previous in-house methodology backed with years of experience. On closer examination, however, there are areas where significant improvement can be made. Improvement opportunities exist for current processes in all phases of product development and manufacture. Better processes result in substantial reduction in cost and time. One of the areas was a close examination of the certification process relating to aircraft icing. Until 1990 an airframe manufacturer was required to fly the airplane through the cloud characterized by the FAA regulation (FAR Part 25) to obtain realistic ice shapes on relevant airplane parts, such as wings, horizontal and vertical tails and ram air turbines, etc. Based on the shapes of accreted ice during flight, molds were prepared. Demonstration of handling qualities is carried out with the shapes derived from the natural icing tests, attached to appropriate locations of the airplane. Flight testing of an airplane to extract the ice shapes in order to estimate the performance degradation and demonstration of airworthiness is a very tedious and expensive process. The Boeing Company, with the support of the FAA, proposed to simplify the airworthiness certification process on aircraft icing. The first part of the process is the extraction of the shape of ice accretion on airplane components. The FAA has issued guidelines for the development of ice shapes in the wind tunnel instead of by flight testing. The FAA emphasized that in order to establish 'certifiable' quality data, the flow qualities of the new tunnel must be equal to or superior in comparison to the NASA Lewis Icing Research Tunnel. The Aerodynamics Laboratory and Mechanical Systems Laboratory of the Boeing Company decided to modify an existing low-speed research tunnel to include icing test capability in addition to conducting basic low-speed aerodynamic research. In order to achieve good flow quality, particularly through the modification of the existing facility, the wind tunnel designer is faced with interesting design challenges. This paper describes some unique designs of the tunnel components and the results of the calibration.

The results of integrated usage of mathematical and physical models to develop aerodynamic lay-outs of altitude and sea-level test cell components to test aviation engines are presented in the report. Performances of dissipative layers in the intake manifold are investigated. New schemes of effective gas flow mixing are developed. The method for pressure control by inducing jets in the pressure cell is given. The basic principles for engine simulators creation are shown.

The European Transonic Windtunnel ETW offers flight/near flight Reynolds numbers. This paper addresses the definition of the basic specification and the expansion of this basic specification into an overall aerodynamic design and concept of control of the facility. The rationale used in the definition of various tunnel components is explained and an overview of some of the studies and calculation methods employed to achieve the design of different sections of the

tunnel are given. The need of test rigs is discussed and some details of the use of the pilot facility PETW in the development of the design are presented. The calibration methods and calibration results showing that the design was successfully implemented are outlined and show the excellent quality that is currently being achieved and demonstrate that the design concept works up to full flight Reynolds numbers.

CONTROL AND MATHEMATICAL MODEL OF TRANSONIC WIND TUNNELS MODELISATION ET PILOTAGE DES SOUFFLERIES TRANSSONIQUES

Gobert, J. L., Office National d'Etudes et de Recherches Aerospatiales, France; Jun. 1997; 8p; In French; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Presently, a large part of wind tunnel testing concerns the subsonic and transonic ranges for civil transport aircraft; one particular topic in such type of tests is that the flow parameters (Mach number, pressure, temperature) require to be controlled with a high level of accuracy. Then, today's wind tunnels shall be equipped with an efficient control system capable to take the best of their performances. During the acquisition of data on the model, the flow parameters shall be maintained within small tolerances, leading to a restricted number of tests performed with a high level of quality in very well defined conditions. The operations of interpolation to be carried out during data post-processing are minimized and the task of the aerodynamicists while scaling up the results to the actual flying conditions shall be easier. On another hand, dead times during the transition periods when going from one set point to another one shall be reduced to keep the running costs as low as possible. This document presents a control technic which was originally developed at ONERA and then adapted, improved and implemented in a recently built and large facility, the European Transonic Wind tunnel ETW erected in Cologne (Germany). During the first years of the ETW design, a computer dynamic model of the facility has been developed to support the control activities. This model, based on the knowledge of the aerodynamic phenomena present in the wind tunnel circuit, simulates the effects of heat transfers and temperature propagation along the circuit as well as the breathing of the Plenum Chamber. It performs a time simulation of the wind tunnel physical phenomena; at each time step, the parameter variations are integrated using the thermodynamics equations. In a following stage, control laws have been studied to drive the into the wind tunnel control system in order to drive the actual process. Results of tests recorded on the actual plant are included in the document. At the present time, a task is undertaken to enhance the performances of the ONERA S1 and S2 wind tunnels. The way this technic can be adapted to existing wind tunnels in order to trace the possible weaknesses of the facility, to correct them and improve the overall behavior are quickly discussed and supported by results of simulation. It is demonstrated that this type of dynamic model can be used to design or redesign, set up and tune a transonic wind tunnel control system in an efficient and economical way as well as to improve the overall performances. Use of this technique enabled to run the ETW facility almost from the first days in automatic mode minimizing considerably the time required to tune the control system and provide quickly satisfactory results.

ELABORATION OF CRYOGENIC TRANSONIC SHORT-DURATION WIND TUNNEL AT ITAM

Zvegintsev, V. I., Academy of Sciences (USSR), USSR; Omelaev, A. I., Academy of Sciences (USSR), USSR; Jun. 1997; 10p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The research program directed to the transonic cryogenic wind tunnel creation have been carried out at the ITAM. Two variants of short-duration cryogenic wind tunnels have been worked out as paper projects. One of them is constructed as a classic blow-down wind

tunnel. Here the cold air (or nitrogen) is collected within thermoinsulated storage vessels at a pressure up to 20 MPa and temperature 190 K. During a run the gas is flowing into the settling (plenum) chamber wherein its pressure falls down to 1 MPa and temperature to 120 K due to throttling effect. The cold gas flowing out is accompanied by high pressure and ambient temperature air flowing into the accumulator thus practically constant stagnation parameters of flow will be kept during the run. Another variant is constructed as a modified Ludwig tube tunnel. The modification consists of an additional reservoir attached to the high-pressure tube with a perforated baffle (wall) between them. Such a device allows one to eliminate reflected rarefaction waves and to prolong useful running time. An experimental program has been initiated at short-duration impulse gasdynamic facility where the first mentioned variant of transonic wind tunnel was checked out. A transonic flow with good uniformity after throttling device was brought off was achieved during these tests. The experiments carried out at TsAGI (Moscow) allow one to establish the conditions when the reflected wave is eliminated for the second version of the tunnel.

New technology for generation of sub-, trans-, and supersonic gas flows along with technology based on the impulse transonic wind tunnel ITT U-11 (nozzle dia 0.8) operated at TSNIMASH are presented. The most important units and systems of the wind tunnel, test results on flow parameters in the working section and also their comparison with the same parameters for usual intermittent wind tunnels are described. The comparison has shown that suggested technology and the wind tunnel design, which allow to reduce essentially wind tunnel dimensions and power consumption, may be used for development of special rigs for complex investigation of aero-gasdynamic and acoustic characteristics of flight vehicle models with engine jet simulation.

A NEW TOOL FOR SCREEN INTEGRATION IN INTERNAL FLOW SYSTEMS AND ITS APPLICATION TO WIND TUNNEL DESIGN

Seltsam, M. M., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Jun. 1997; 12p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

To consider mesh screens in internal fluid flow a numerical method is modified. A Navier-Stokes method with the standard k-ε turbulence model is employed. The new extended numerical method is applied to wide-angle diffuser flow. The comparison of calculated diffuser flows with experimental results yields the requisite correspondence. The numerical and experimental investigations lead to a modification of the actual windtunnel. After realization of the modification a remarkable reduction of spatial velocity disturbances is achieved. The capability of screens to suppress turbulence is displayed by comparison of turbulence level distributions before and past the optimization of the settling chamber.

The review will be presented on the experimental study of using variable wall porosity for the methodical and productive wind tunnel testing of the aircraft models. Except for brief discussion of present state in this area the main reported results are based on the experience of exploitation of different porous wall test sections of TsAGI T-128 wind tunnel. This facility has 4 interchangeable test sections, each of them equipped with the specially designed variable porous walls according to the testing specialty. For example, test sections N1 and N2 have each 128 controlled sections designed as overlapping porous surfaces with the open area ratio variation from 0 to 18%. Test section N3 is equipped with longitudinally- variable slots, open area ratio changing from 0 to 13%. This test section is used for 2-D airfoil testing and has all the necessary instrumentation: controlled wall boundary layer suction upstream from the model, 2 degree of freedom wake survey mechanism, pressure measurement system for 1200 points on the basis of electronic modules etc. Test section N5 serves for aeroelastic model testing. Adjustable wall porosity is designed only in model location area. It is used not only for wall interference reduction but also as a flow excitation source. As an example of different adaptive-wall test sections, data are presented on two geometrically-similar A4 airfoils tested in the test section N3. Reference model AEDC-2, tested in section N1, is compared to the 1 6-T wind tunnel test of the same model. Also, results of the "flying" strut test in section NS is presented.

ALLEVATION OF AXIAL STATIC PRESSURE GRADIENTS IN 2D PERFORATED TEST SECTION OF IAR BLOWDOWN WIND TUNNEL

Tang, F. C., Institute for Aerospace Research, Canada; Chan, Y. Y., Institute for Aerospace Research, Canada; Jun. 1997; 8p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The complicated flow mechanism in the empty porous 1AR 2D test section including the plenum chamber and downstream diffuser section was studied and postulated. The forward-facing inclined holes in the test section top and bottom walls resulted in the plenum pressure being higher than the test section static pressure. The original test section side walls were too short and a big opening was formed between the test section and the downstream diffuser. The plenum air mass was readily entrained through this opening by the free jet flow formed downstream of the test section. The removal of the plenum air mass from this opening effectively lowered the plenum pressure resulting in the outflow phenomenon in the test section. With the presence of a long side wall extension the opening between the test section and the downstream diffuser section would be shortened. The plenum mass flow was greatly reduced as entrainment was decreased due to a shorter free jet flow. A pressure equilibrium condition between the plenum and the test section was thus established resulting in a constant pressure distribution along the test section. This paper presents the results obtained during the commissioning of this extended side wall configuration and the subsequent modifications made to it. A close to optimum configuration for the IAR 2D test section extension has been found.

The report provides results of experimental evaluation of flow in a transonic wind tunnel with forced suction from the plenum chamber surrounding a perforated test section. It is shown that the test section exit part features an air outflow into the plenum chamber, this decelerates flow, increases pressure, and decreases the Mach number at the entry into the main subsonic diffuser of the wind tunnel. In this case, total pressure losses become notably less. Also reported are results of experimental investigations into operation of a large wind tunnel with the suction system which extends the ranges of Mach and Reynolds numbers and reduces total pressure losses.

ADAPTIVE SLOTS: AN ALTERNATIVE CONCEPT TO REDUCE WALL INTERFERENCE

Quest, J., ETW G.m.b.H., Germany; Nitsche, W., Technische Univ., Germany; Mignosi, A., Centre d'Etudes et de Recherches, France; Jun. 1997; 10p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

An alternative concept to reduce wall interference in wind-tunnel testing by means of adaptive slots is presented and its benefits are highlighted by means of experimental as well as numerical investigations. The qualification of the 3d-NAVIER-STOKES code employed for the parametric numerical investigations is demonstrated by comparison with Laser 2-focus and surface pressure measurements. The effectiveness of a single central adaptive slot is proved for a convex profile as well as for a body of revolution by referencing the results to 2d wall adaptations. For a simplified 3d slot, adaptation featuring 6 slots on each top and bottom wall have better agreement with the free-stream solution than for the 2d wall adaptation that was achieved.

PROGRESS IN DETERMINING WALL-INDUCED INTERFERENCE IN SLOTTED-LINER WIND TUNNELS USING MEASURED WALL CONDITIONS

Freestone, M. M., City Univ., UK; Sykes, D. M., City Univ., UK; Jun. 1997; 12p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Further work and analysis relating to a previously proposed scheme for determining slotted-liner wall-induced interference at subsonic speeds are presented. The scheme utilises measurements of wall (slat) pressures and values of the velocity-component normal to the liner measured in the plane of the liner along a slot centre line. This flow component is measured by a probe, and longitudinal distributions of the normal velocity are obtained both from traverses and multiple point measurements. With a three-dimensional test configuration, measurements would be made on each slat and slot, but in the present tests with a two-dimensional aerofoil the slats and slots in each wall (roof and floor) are assumed to behave equally. Assessment of the results of utilising the scheme is based on comparisons of aerofoil pressures at corrected conditions of Mach number and (three-quarter chord) incidence. More detailed assessment by other means is suggested. The scheme appears reliable for the range of test conditions undertaken, and these more than adequately cover conditions likely to be found in the large three-dimensional test facilities for which the method is intended.

AERODYNAMIC DESIGN OF AXIAL-FLOW FANS FOR SUBSONIC WIND TUNNELS

Brusilovskiy, I. V., Tsentralni Aerogidrodinamicheskii Inst., Russia; Jun. 1997; 8p; In English; See also 19970029162; Copyright Waived; Avail:

CASI; A02, Hardcopy; A04, Microfiche

The report highlights features of wind tunnel fans with axial annular diffusers, as well as relations for defining fan parameters (including the total pressure loss factor) with the aid of the equivalent diffuser length and the total pressure loss coefficient of a planar diffuser. Test data on planar and annular diffusers (including data on the annular diffusers tested with fans) are compared. Foundations of fan aerodynamic design are provided; this is subdivided into two principal stages: (1) determining the basic parameters (volume-averaged axial flow-speed coefficient, theoretical pressure coefficient, and two new parameters: the prewhirl upstream of an impeller and the residual whirl downstream of an outlet guide vane) as well as the fan hub diameter; (2) shaping the guide vanes and impeller blading. The operational envelope is outlined; taking parameters in this domain ensures creating a fan with really separation free flow about blades both at a rated regime at a maximum possible efficiency and over a certain domain around the rated regime. The design parameters are selected, and efficiency evaluated, in the general form for a complete fan configuration comprising an inlet guide vane (IGV), the impeller, and an outlet guide vane (OGV). Results for configurations without one or two guide vanes are the corresponding particular cases. Expressions for optimizing the design parameters and the respective efficiency are derived. Theoretical and experimental values of the two new parameters of flow whirl are compared. The shaping procedure (i.e., defining the airfoil setting angle, shape, curvature, the blade array spacing, rated airfoil angle of attack, total number and shapes of the blades) is based on generalized test data; the relations allow for radial blading-variation and the "distance" to the maximum pressure on the fan characteristic curve. Airfoil setting angles and radial variation of airfoil curvature are proposed to be derived from theoretical data on airfoil arrays on the basis of a unified method for all bladed components with arbitrary array density. This aerodynamic design method developed at GOSNITs TsAGI has been used and improved for more than 45 years and has been comprehensively verified.

The experience accumulated at the Central Aerohydrodynamic Institute for many years in calculating, designing, and running wind tunnels in which pressure difference is produced by a jet ejector-compressor, is analyzed. Theories for optimal gas ejectors and their systems are given, new schemes of gas ejectors of improved performance are discussed, and problems of improving economic efficiency of the 'wind tunnel-gas ejector' system are considered. Examples of successful use of ejectors as major drivers of subsonic, trans-, and hypersonic wind tunnels are presented.

In this paper the features of air flow in a diametral fan (DF) contour and its aerodynamic characteristics are reported. The field of application for the DF in the wind tunnels is determined. The results of experimental investigations of DF geometrical parameters effect on DF aerodynamic parameters are given. The performance data of the MBDB Raduga compact subsonic wind tunnel and the Laboratory Training Aerodynamic Complex (ULAK) for Technical Schools which is developed on its base are offered. The method of approximate simulation of following a body contour with a liquid with free surface in a wide range of $F(z)$ numbers for subsonic wind tunnels is proposed, and the possibility of DF use in the installations of this type is considered.

Results of experimental study of various configurations of the subsonic wind tunnel test section with a free jet and Eiffel chamber are presented in order to determine its optimum variant corresponding to minimum values of velocity and pressure pulsation, hydraulic losses and flow non-uniformity in the model location zone. At a given reduced jet length the parameters of the test section configuration were provided by varying the relation of the diffuser entry section area to the nozzle exit section area and by variations of the collector placed in front of the diffuser. Different forms of the collector were studied: one-piece contracting collector, contracting collector adjusted along the angle and collector with parallel walls. From the collectors investigated the best in the aggregate of the flow efficiency criteria is the one-piece contracting collector with an angle of inclination of walls $\alpha(c)$ is approx. equal to 14 degrees and an optimum relative value of the gap between it and the diffuser is approx. equal to 0.2.

MODEL AND FULL SCALE INVESTIGATIONS OF THE LOW FREQUENCY VIBRATION PHENOMENA OF THE DNW OPEN JET

Holthuisen, H., Duits-Nederlandse Windtunnel, Netherlands; Kooi, J. W., Duits-Nederlandse Windtunnel, Netherlands; Jun. 1997; 8p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The German-Dutch Wind Tunnel DNW is a large low speed wind tunnel with three different sized closed and one open test sections

(Open Jet). Already during the first calibration phase of the Open Jet in 1981, it soon became clear that the maximum jet velocity was not limited by the available fan power, but by the maximum allowable vibrations of the Test Hall which surrounds the Open Jet. Due to low-frequency pressure fluctuations generated by the Open Jet, the vibrations reached levels which could become critical for the Test Hall structure. In order to be able to increase the maximum velocity beyond this 80 m/s an extensive research programme was executed in the 1:10 scaled pilot wind tunnel of DNW. The objective of this programme was to find the sources of the observed low frequency pressure fluctuations and to verify different configurations for their potential to reduce the vibration level. The tested configurations included a number of well-known nozzle modifications as well as a new configuration with so-called tetrahedrons. The effect of modifications of the collector geometry and the effect of extra bleeding was also investigated. After completing the tests in the pilot wind tunnel, the most promising solutions were tested in the DNW. It turned out that the results found in the two wind tunnels correlated very well. A surprising outcome was that in both tunnels the tetrahedrons increased the jet speed without a noticeable reduction of the usable cross section of the Open Jet and without increasing the acoustic background noise level.

SELF-OSCILLATION FLOW CONTROL IN FREE-JET WIND TUNNELS

Ginevsky, A. S., Tsentralni Aerogidrodinamicheskii Inst., USSR; Jun. 1997; 12p; In English; See also 19970029162
Contract(s)/Grant(s): RFFI-96-02-19577; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

In wind tunnels with the open test section strong, self-oscillations arise at certain flow velocities which are accompanied by a sharp increase of pressure and velocity pulsations in the test section. Traditional methods of self-oscillation control do not provide complete suppression. In the work presented the acoustic methods of self-oscillation control (their suppression or generation), based on the coherent jet structure response to periodic excitation have been investigated. The experiments were carried out in four wind tunnels with different outer diameters of the exhaust nozzle $d = 0.15\text{--}2.2$ m.

TURBULENCE AND NOISE CRITERIA AND THEIR IMPLEMENTATION IN NWTC-TYPE WIND TUNNELS

Reshotko, Eli, Case Western Reserve Univ., USA; Saric, William S., Arizona State Univ., USA; Nagib, Hassan M., Illinois Inst. of Tech., USA; Jun. 1997; 14p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper considers the establishment of turbulence and noise criteria as a function of Mach number and total pressure for utilitarian low-speed and transonic wind tunnels of the National Wind Tunnel Complex (NWTC) class facilities such that boundary-layer transition models likely to be tested in them will not be contaminated by the flow environment. Aside from the NWTC tunnels themselves, the ideas in this paper apply to upgrades and revisions of existing tunnels such as the NASA-Ames 11-foot Unitary Tunnel and the AEDC 16T tunnel.

les, France; Rancarani, G., Office National d'Etudes et de Recherches Aérospatiales, France; Delery, J., Office National d'Etudes et de Recherches Aérospatiales, France; Arnal, D., Centre d'Etudes et de Recherches, France; Jun. 1997; 16p; In French; See also 19970029162; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The R1Ch blow down wind tunnel was recently converted into a quiet supersonic wind tunnel at Mach 3. In order for the boundary layers on the nozzle wall to remain laminar, the following tasks were accomplished: noise minimization coming from the upstream circuit, realization of suction upstream of the throat to eliminate the boundary layer in the contraction, optimization of the nozzle shape calculated in order to reduce Görtler vortex, and realization of a surface quality to avoid triggering of transition due to the roughness. The theoretical, numerical and technological works resulting in the realization of the wind tunnel, are presented with the description of the facility. A preliminary validation of the wind tunnel was done with: measurement of pressure fluctuations in the stilling chamber, probing of boundary layer upstream of the nozzle throat, probing of pitot pressure and flux measurement on plane plate in the test section, and probing of boundary layer in the nozzle exit plane.

CHARACTERISTICS OF THE NASA-AMES LAMINAR FLOW SUPERSONIC WIND TUNNEL FOR UNIQUE MACH 1.6 TRANSITION STUDIES

Wolf, Stephen W. D., MCAT Inst., USA; Laub, James A., NASA Ames Research Center, USA; Jun. 1997; 18p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Flow quality measurements have been performed in the unique Laminar Flow Supersonic Wind Tunnel (LFSWT) to examine both mean and dynamic characteristics. The intent was to provide the necessary flow information about this ground test facility, to support meaningful transition research at Mach 1.6 and flight unit Reynolds numbers. This paper is intended to assist other experimentalists with similar goals of characterizing low-supersonic test environments. An array of instrumentation has been used to highlight the importance of proper selection of pressure instruments and data acquisition procedures. We conclude that the test section is low-disturbance (based on classical standards of pressure disturbances less than 0.1% with no specified data bandwidth), and has uniform flow. This is confirmation that the quiet design features of the LFSWT are effective. However, characterization of the test section flow over a 0.25k-50k bandwidth shows that the disturbance levels can be greater than classical standards particularly for stagnation pressures less than 9.5 psia (0.65 bar) with low stagnation temperatures. Variability of the flow disturbances in the settling chamber and test section is contained in a narrow frequency bandwidth below 5k Hz, which is associated with resonant frequencies from the pressure reduction system. So far, these disturbances have not impacted transition along the tunnel walls or a 10 degrees cone. However, continual vigilance is required to maintain a known low-disturbance environment for transition research in the LFSWT. Furthermore, the formation of standards for flow quality measurements is strongly recommended, so that transition research can be better isolated from tunnel disturbances.

FLUCTUATION CHARACTERISTICS OF FLOWS IN TEST SECTIONS OF HIGH-SPEED WIND TUNNELS

Lebiga, V. A., Academy of Sciences (USSR), USSR; Zinoviev, V. N., Academy of Sciences (USSR), USSR; Jun. 1997; 10p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The results of fluctuation structure study in test sections of wind tunnels in the wide range of velocity (from large subsonic up to supersonic) are presented in this paper. A correlation between characteristics of the boundary layer on the test section walls of the supersonic wind tunnel with fluctuations in the flow core is shown. Detailed characteristics of fluctuations in ventilated test sections are given for different types of walls (perforated, slotted, smooth rigid). The constant current hot-wire anemometer and developed at ITAM technique have been used for fluctuation measurements and interpretation of the results.

This report gives results of theoretical considerations and experimental research on gas flows in axisymmetric nozzles of sub- and transonic wind tunnels. Two classes of nozzle transverse contours were investigated at test section flow velocities corresponding to Mach numbers of $M(\infty) = 0.1-1.0$. Cross-section shapes for the first class of contours were calculated using the Witoszinski equation, and for the second class they were determined by the equations considered in the present report. It is shown that the flow pattern which takes place in the considered nozzles especially at nozzle entries, is not one dimensional. It is found, that the Witoszinski contour is unacceptable for a practical implementation of representative contraction factor and nozzle length-to-diameter ratio values; the reason is unacceptable negative longitudinal velocity gradient value on the wall near the nozzle entry, which can lead to boundary layer separation. Similar results are given for a gas flow in the nozzles having rectangular, circular, and octagonal transverse contours and also in the nozzle having circular transverse entry contour and octagonal transverse exit contour.

METHOD FOR THE CALCULATION OF 2D SUPERSONIC VARIABLE NOZZLE CONTOURS

Verkhovsky, V. P., Tsentralni Aerogidrodinamicheskii Inst., Russia; Jun. 1997; 6p; In English; See also 19970029162; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The report considers a supersonic adjustable nozzle including a rigid acceleration-section and a flexible smoothing-section. These are proposed to be designed by the method that ensures a Mach number field (within 1% error) in the characteristic rhomb for a certain Mach number range, while requiring only a few adjustment points (where hydraulic actuators are attached). The method is based on numerical analysis of flow in a nozzle whose flexible section is described by a cubic spline. Consideration is given to nozzles with a maximum angle of the acceleration section of 10 through 18 degrees, which are intended to provide the exit Mach number of 1.2 to 4.0. It is shown that using three or four adjustment points in nozzles with inclination angle of less than 12 degrees ensures the characteristic-rhomb flow nonuniformity of no greater than 0.5%, and for angle less than 17 degrees the flow nonuniformity does not exceed 1%. In order to allow for air

09 RESEARCH AND SUPPORT FACILITIES (AIR)

viscosity in nozzles designed to M less than 5.0, a general relation between the boundary layer displacement thickness and the Mach number is proposed.

SURVEY OF AEROTHERMODYNAMICS FACILITIES USEFUL FOR THE DESIGN OF HYPERSONIC VEHICLES USING AIR-BREATHING PROPULSION

Arnold, James O., NASA Ames Research Center, USA; Deiwert, George S., NASA Ames Research Center, USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 16p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

This paper surveys the use of aerothermodynamic facilities which have been useful in the study of external flows and propulsion aspects of hypersonic, air-breathing vehicles. While the paper is not a survey of all facilities, it covers the utility of shock tunnels and conventional hypersonic blow-down facilities which have been used for hypersonic air-breather studies. The problems confronting researchers in the field of aerothermodynamics are outlined. Results from the T5 GALT tunnel for the shock-on lip problem are outlined. Experiments on combustors and short expansion nozzles using the semi-free jet method have been conducted in large shock tunnels. An example which employed the NASA Ames 16-Inch shock tunnel is outlined, and the philosophy of the test technique is described. Conventional blow-down hypersonic wind tunnels are quite useful in hypersonic air-breathing studies. Results from an expansion ramp experiment, simulating the nozzle on a hypersonic air-breather from the NASA Ames 3.5 Foot Hypersonic wind tunnel are summarized. Similar work on expansion nozzles conducted in the NASA Langley hypersonic wind tunnel complex is cited. Free-jet air-frame propulsion integration and configuration stability experiments conducted at Langley in the hypersonic wind tunnel complex on a small generic model are also summarized.

TEST FACILITIES FOR LARGE RAMJETS

Koschel, W. W., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Heitmeier, F., Daimler-Benz Aerospace A.G., Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 10p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Within the German Hypersonics Technology Program (GHTP) a subscale ramjet was to be ground tested in a free jet configuration. The propulsion system selection process for a hypersonic experimental flight vehicle will be briefly reviewed. A ramjet type propulsion system with subsonic combustion was chosen as the baseline configuration. The rationale of technology and component development will be presented. The final goal of the program was a ramjet test in the simulated flight Mach number range from Ma = 3.5 up to Ma = 6.8 in order to demonstrate the engine's steady state operation and thrust capability. A general concept for the ramjet ground testing was developed specifying as well the operational requirements for the engine characteristics as the test and measurement plan. A ramjet propulsion system with a ram combustor diameter of 500 mm was designed as the demonstrator engine. Based on the predefined specifications an evaluation of existing large scale test facilities was made including a total of 11 existing facilities in the USA, in Russia and in France. Engine installation and necessary adaptation of existing hardware were studied and discussed with the operators in detail. Major results of this facility evaluation study and lessons learned will be presented in the paper. The APTU wind tunnel of the AEDC at Tullahoma was finally selected for the planned tests of the full engine. Due to funding restric-

tions only the ram combustor with the variable geometry nozzle could be demonstrated in operation in the connected-pipe test facility at Ottobrunn in Germany.

NASA AND ESA GROUND FACILITY SIMULATIONS OF SHUTTLE ORBITER AEROTHERMODYNAMICS

Muylaert, J., European Space Agency. European Space Research and Technology Center, ESTEC, Netherlands; Rostand, P., Dassault Aviation, France; Rapuc, M., Dassault Aviation, France; Paulson, J., NASA Langley Research Center, USA; Brauckmann, G., NASA Langley Research Center, USA; Trockmorton, D., NASA Langley Research Center, USA; Steijl, R., Technische Univ., Netherlands; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 3; 16p; In English; See also 19980018672; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The paper reviews a combined numerical and experimental activity on the Shuttle Orbiter, first performed at NASA Langley within the OEX workshop and subsequently at ESA, as part of the AGARD FDP WG 18 activities. The study at Langley was undertaken to resolve the pitch up anomaly observed during the entry of the first flight of the Shuttle Orbiter. The facilities used at NASA Langley were the 15-in. Mach 6, the 20-in. Mach 6, the 31-in. Mach 10 and the 20-in. Mach 6 CF4 facility. The paper focuses on the high Mach, high altitude portion of the first entry of the Shuttle where the vehicle exhibited a nose-up pitching moment relative to pre-flight prediction of ($\Delta C_{(sub m)} = 0.03$). In order to study the relative contribution of compressibility, viscous interaction and real gas effects on basic body pitching moment and flap efficiency, an experimental study was undertaken to examine the effects of Mach, Reynolds and ratio of specific heats at NASA. At high Mach, a decrease of gamma occurs in the shock layer due to high temperature effects. The primary effect of this lower specific heat ratio is a decrease of the pressure on the aft windward expansion surface of the Orbiter causing the nose-up pitching moment. Testing in the heavy gas, Mach 6 CF4 tunnel, gave a good simulation of high temperature effects.

THE USE OF TECHNOLOGY DEMONSTRATORS TO REDUCE SYSTEM ACQUISITION COST

Moorhouse, David J., Wright Lab., USA; Paul, Donald B., Wright Lab., USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 1; 12p; In English; See also 19980033517; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

In the definition and design of a new aircraft system, the choice of technologies to be incorporated is a major decision. Although the latest technology usually yields the maximum (predicted) performance, the readiness of each technology must be carefully assessed. The less the readiness or maturity, the greater the risk to development schedule and cost. There is a premium therefore, on demonstrations that validate the appropriate maturity of each technology. For some things ground demonstration is adequate to reduce the risk to an acceptable level. Some technologies, on the other hand, can only be validated through flight demonstration. Technology flight demonstration programs have been accomplished in many forms, explicit prototype vehicles, the X-plane series from the X-1 to the X-31 and technology demonstrations with an explicit military objective.

ASTRONAUTICS (GENERAL)

Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

T2 is an induction driven wind tunnel in which Reynolds number variations are obtained by increasing the total pressure ($P(\text{sub } t) = 1,4$ to 3bar) and reducing the total temperature ($T(\text{sub } t) = 300$ to 110K). The flow is driven by an injection of dry air at ambient temperature and cooled by another injection of liquid nitrogen. Advanced development of conventional techniques and modern measurement techniques have been performed for low-temperature cryogenic flows. This paper presents the evolution of the specific tools sometimes developed, always tested and mainly used for different 2D or 3D flows at ambient and cryogenic conditions. Firstly, it gives the developments performed in the field of anemometer and pressure probes to measure the flow quality of the cryogenic wind tunnel. Secondly, it describes the use of an infrared technique for the qualification of the boundary layer transition on 2D and 3D models. Finally, this paper presents some L.D.A. typical 2D and 3D measurements at ambient condition and the adaptation of this velocity measurement device to work in cryogenic conditions.

DEVELOPMENT OF PIV FOR TWO AND THREE COMPONENT VELOCITY MEASUREMENTS IN A LARGE LOW SPEED WIND TUNNEL

Bearman, P. W., Imperial Coll. of Science Technology and Medicine, UK; Harvey, J. K., Imperial Coll. of Science Technology and Medicine, UK; Stewart, J. N., Imperial Coll. of Science Technology and Medicine, UK; May 1998; 10p; In English; See also 19980203985; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The use of particle image velocimetry, PIV, to make measurements in flows generated around models in a low speed wind tunnel is described. The tunnel test section employed is 3m wide by 1.5m high. The problems associated with using PIV in air at large scale, and how they can be overcome, are discussed. Stereoscopic PIV is used to measure all three components of velocity in planes across a flow. Errors due to parallax that are present in velocity components measured in the plane of a light sheet when there is an accompanying flow through the sheet, are corrected. The flows studied are generated by a 1/8th scale passenger car model and a 1/8th scale model of an aircraft with a wing sweep of 70 degrees. It is found that a reasonable estimate of a mean flow field can be obtained by averaging as few as ten instantaneous spatial distributions of velocity.

A QUANTITATIVE 2D DENSITY MEASURING SYSTEM USING UV RAYLEIGH SCATTERING AT AN ATMOSPHERIC WIND TUNNEL
Jakiel, C., Universitaet der Bundeswehr, Germany; Fiedler, K., Universitaet der Bundeswehr, Germany; Sieber, O., Universitaet der Bundeswehr, Germany; May 1998; 10p; In English; See also 19980206002; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

An optical density measuring system based on Rayleigh scattering was installed in an atmospheric wind tunnel. The system monitors the scattered light induced by a laser sheet irradiating the flow field behind a plane VKI-1 turbine cascade. The measuring procedure needing very short time is based on a relative measurement. This paper presents a brief summary of fundamentals, the experimental setup, and the measurement principles. As experimental result plane density distributions at different blade heights are given for subsonic and transonic flow. The experimental data is compared to results of a three-dimensional Navier-Stokes calculation.

Volume 1, the summary volume, of the report of the NATO Advisory Group for Aerospace Research and Development (AGARD) study: 'Aerospace 2020'. This study explores the most advanced technologies, relevant to aerospace, being researched and developed in laboratories today. The study focuses on the most promising current technologies and the organizational and tactical consequences they will have at the field and system levels, over the course of the next 25 years. Topics include: a discussion of the impact of proliferation, human-machine interaction, synthetic environments, directed-energy weapons, information technologies, unmanned tactical aircraft, sub-orbital launchers, hypersonic missiles, and a discussion of affordability issues. Technologies are assessed from the viewpoints of both potential capabilities and threats. Observations and recommendations are presented.

I am very pleased to have been asked to give the scene setting presentation on the NATO use or projected use of space. NATO has been in the satellite business since the mid 1960s. At this point however, I believe it would help if I was to stress that NATO's primary interest lies in the use of satellites for communications (SATCOM), although we have given consideration to the possible use of satellites for surveillance. Many of you may be aware of one of our latest require-

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE)

ments for battlefield intelligence information which will most probably be met through a new program entitled Alliance Ground Surveillance (AGS).

Volume II, is the main document of the "Aerospace 2020" report by the NATO Advisory Group for Aerospace Research and Development (AGARD). This study examines the most advanced aerospace technologies currently under development or study. It centers on what are now considered to be the most promising technologies, as well as structural and tactical consequences they will have on the theater of operations and on systems over the next 25 years. Subjects covered include the impact of proliferation, man-machine interaction, synthetic environments, directed-energy armaments, information technology, unpowered tactical aircraft, suborbital launchers, hypersonic missiles as well as a discussion of acceptable acquisition costs. The technologies are evaluated from two viewpoints: as assets and as threats. Remarks and recommendations are presented.

DEVELOPMENT OF A MODAL TESTING SUPPORT SYSTEM FOR SPACE-BASED RADAR SATELLITE STRUCTURES

Mctavish, D. J., Dynacon Enterprises Ltd., Canada; Sincarsin, G. B., Toronto Univ., Canada; Soucy, Y., Canadian Space Agency, Canada; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 12 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The development of a modal testing support system (MTSS) for the Canadian Department of National Defence (DND) is described. The MTSS consists of both hardware and software elements which will augment existing testing facilities of the Canadian Space Agency. A critical capability of the MTSS is the ability to deal methodically with structures so large and flexible that they are unable to properly support their own weight in a 1-g environment. The structures of the envisioned space-based radar (SBR) satellites fall into this class. The performance of such a surveillance system depends upon satisfactory structural dynamic response of the spacecraft, among other factors. The output of the modal testing process is an experimentally validated structural model which becomes a valuable tool for predicting dynamic

behavior. to support the validation of this system, a number of test structures are being produced which will emulate the structural behavior of a generic SBR mechanical system.

HYPERSONIC AERODYNAMIC/AEROTHEMAL TEST FACILITIES AVAILABLE IN EUROPE TO SUPPORT SPACE VEHICLE DESIGN
Vennemann, D., Centre National d'Etudes Spatiales, France; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 14 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The paper gives an overview of the major hypersonic wind-tunnels available in Europe for the determination of aerodynamic characteristics, like forces and moments, or for the measurement of heat transfer rates and heat transfer distributions of space vehicle configurations. The following facilities are presented: (1) the blow-down wind-tunnel S4 of ONERA at Modane, France; (2) the longshot facility of the Von Karman Institute at Rhode-Saint-Genese, Belgium; (3) the shock tunnel TH2 of the Aachen Technische Hochschule RWTH, Germany; (4) the piston-driven wind-tunnel HEG of DLR at Gottingen, Germany; and (5) the hot shot test facility F4 of ONERA at Le Fauga, France. The operating principle of each of these facilities is described, the performance characteristics are given, and the main features of their construction are highlighted. This is followed by a short presentation of some advanced optical measurement techniques available for use in the facilities like the electron beam technique, the laser induced fluorescence (LIF) technique, the tunable laser diode, and holographic interferometry.

The report contains the description of proposal on development and use of space system intended for direct (contact) exploration of such natural hazards as, for example, tropical cyclones or ozone hole which are heavy influences on human life activity. This system would be developed on base of Russian (former Soviet) SS-19 ICBM, which should be removed from battle duty according to the START Treaty. Recently developed on the basis that ICBM Russian 'Rockot' launch vehicle can deliver with high accuracy to hazard region up to 50 reentry probes which should transmit the information through space, airborne or sea retransmitters. That efficient collection of information on atmo-

sphere conditions in altitude range of 40...0 kilometers should be the effective tool for investigation of large-scale natural phenomena which are very dangerous for people and economics of Earth.

Ariane 44LP/V64 was launched on 17 June 1994 when it placed two microsatellites, Space Technology Research Vehicle (STRV)-1a and STRV-1b, into geostationary transfer orbit (GTO). This paper describes the technology demonstration experiments on the spacecraft, with particular emphasis on the theoretical and empirical models used for design and testing, and presents some early data as evidence that the mission objectives will be met.

Most satellites are designed to optimize their operability in space; optimizing their ability to arrive in space is secondary. Regardless of how well a satellite system is produced it cannot have the opportunity to operate if the launch vehicle it was designed for is unavailable. Access to space can be optimized by providing launch vehicles with a 'fitness for use' approach. The ability to launch a satellite on different launch vehicles with minimal or no modifications to either the satellite or the launch vehicle is highly desirable in both the defense and emerging commercial markets.

CAPRICORNIO LAUNCHER: AN APPROACH TO A MODULAR AND LOW COST SOFTWARE ARCHITECTURAL DESIGN

Gallego, Jose M., Instituto Nacional de Tecnica Aeroespacial, Spain; Rico, Jose E., Instituto Nacional de Tecnica Aeroespacial, Spain; Jul. 1997; 10p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper introduces the Capricornio Program by means of describing the vehicle requirements, architecture and guidance philosophy as well as the required ground facilities. Later and in a more detailed way, Requirements Specifications and TopLevel Design of CAPRICORNIO Launcher Software are presented, with a reference to the static and dynamic behavior of the chosen architecture. Hardware interaction aspects are omitted. Regarding the Ground Control Computer Software, an overview of the Rapid Prototyping Technique through Lab VIEW is presented with a look to the first results. This article shows how a low cost software is being developed with a high modularity and flexibility degree allowing an easy migration among demonstrator vehicles (ARGO) and finally, the CAPRICORNIO launcher.

19960003903 Deutsche Aerospace A.G., Munich, Germany
FLIGHT TESTING VEHICLES FOR VERIFICATION AND VALIDATION OF HYPERSONICS TECHNOLOGY

Sacher, Peter W., Deutsche Aerospace A.G., Germany; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 13 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Hypersonics technology has obtained renewed interest since various concepts for future completely reusable Space Transportation Systems (STS) using airbreathing propulsion for the parts of atmospheric flight have been proposed in different countries (e.g. US, CIS, Japan, France, Germany, and UK). to cover major developments in those countries, AGARD FDP has formed the Working Group 18 on 'Hypersonic Experimental and Computational Capabilities - Improvement and Validation'. of major importance for the proof of feasibility for all these concepts is the definition of an overall convincing philosophy for a 'hypersonics technology development and verification concept' using ground simulation facilities (both experimental and numerical) and flight testing vehicles. Flying at hypersonic Mach numbers using airbreathing propulsion requires highly sophisticated design tools to provide reliable prediction of thrust minus aerodynamic drag to accelerate the vehicle during ascent. Using these design tools, existing uncertainties have to be minimized by a carefully performed code validation process. to a large degree the database required for this validation cannot be obtained on ground. In addition thermal loads due to hypersonic flow have to be predicted accurately by aerothermodynamic flow codes to provide the inputs needed to decide on materials and structures. Heat management for hypersonic flight vehicles is one of the key-issues for any kind of successful flight demonstration. This paper identifies and discusses the role of flight testing during the verification and validation process of advanced hypersonic technology needed for flight in the atmosphere with hypersonic Mach numbers using airbreathing propulsion systems both for weapons and space transportation systems.

FUTURE SPACE TRANSPORTATION SYSTEMS AND THEIR POTENTIAL CONTRIBUTION TO THE NATO MISSION

Whitehair, Chester L., Aerospace Corp., USA; Wolfe, Malcolm G., Aerospace Corp., USA; Jun. 1997; 12p; In English; See also 19970026418; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Space systems are now an essential part of military operations and, in the Western World, the reliability and operability of these systems is crucial to the success of the military mission. At the same time, overall western military budgets universally are suffering severe cuts. Although the Cold War is over, the threat to world peace, if anything, has increased rather than decreased. The threat is also much more difficult to contain. The well-defined, single-source, monolithic threat of the Cold War has been replaced by a multi-source, distributed threat. The questions arise - how has the NATO peace-keeping or warfighting mission changed in response to the new world environment; are the space resources of the Cold War the ones that can be effective in the future; how can dwindling government military budgets be augmented by the use of internationally shared or commercial space assets; and how can emerging space technologies and capabilities, whether developed by the government or the commercial sector, contribute to world peace?

19950023204 Army Medical Command (18th), Unit 15281.; USA
REQUIREMENT FOR ONBOARD TELEMETRY EQUIPMENT
Granger, Mathew S., Army Medical Command (18th), USA; Urbauer, Craig L., Army Medical Command (18th), USA; AGARD, Recent Issues and Advances in Aeromedical Evacuation (MEDEVAC); Feb 1, 1995, 5 p; In English; Copyright; Avail: CASI; A01, Hardcopy; A02, Microfiche

The use of onboard telemetry equipment in EMS ground and air ambulances has made significant inroads in the civilian sector. This article reviews data from 661 patients evacuated by UH-60A helicopters in the Republic of Korea from June 1993 through May 1994. Patient categories, enroute care provided, and patient outcomes are analyzed to determine if onboard telemetry equipment would have improved enroute care provided or patient outcome. The data indicates onboard telemetry would have been of marginal utility and would not have affected patient outcomes. It is the conclusion of the authors that onboard telemetry equipment would be of limited value in military aeromedical evacuation operations.

GPS-BASED NAVIGATION FOR SPACE APPLICATIONS
Champetier, C., MATRA Marconi Space, France; Duhamel, T., MATRA Marconi Space, France; Frezet, M., MATRA Marconi Space, France; AGARD, Dual Usage in Military and Commercial Technology in Guidance and Control; Mar 1, 1995, 9 p; In English; See also 19950026705; Copyright; Avail: CASI; A02, Hardcopy; A02, Microfiche

We present in this paper a survey of the applications of the GPS (global positioning system) system for spacecraft navigation. The use of the GPS techniques for space missions is a striking example of dual-use of military technology; it can bring vast improvements in performances and, in some cases, for a reduced cost. We only deal in this paper with the functional aspects and performances of GPS uses without addressing the issues of hardware implementation where current developments are leading to an increased miniaturization of the GPS receiver hardware. We start this paper with a general overview of the GPS system and its various uses for space missions. We then focus on four areas where MATRA MARCONI Space has conducted detailed analyses of performances: autonomous navigation for geostationary spacecraft, relative navigation for space rendezvous, differential navigation for landing vehicles, absolute navigation for launchers and reentry vehicles.

Spacecraft operation depends upon knowledge of vehicular position and, consequently, navigational support has been required for all such systems. Technical requirements for different mission trajectories and orbits are addressed with consideration given to the various tradeoffs which may need to be considered. The broad spectrum of spacecraft are considered with emphasis upon those of greater military significance (i.e., near earth orbiting satellites). Technical requirements include, but are not limited to, accuracy; physical characteristics such as weight and volume; support requirements such as electrical power and ground support; and system integrity. Generic navigation suites for spacecraft applications are described. It is shown that operational spacecraft rely primarily upon ground-based tracking and computational centers with little or no navigational function allocated to the vehicle, while technology development efforts have been and continue to be directed primarily toward onboard navigation suites. The military significance of onboard navigators is shown to both improve spacecraft survivability and performance (accuracy).

KNOWLEDGE-BASED SYSTEMS APPLICATIONS FOR AUTOMATING SPACECRAFT OPERATIONS: USERS FEEDBACK AND LESSONS LEARNED

Darroy, Jean-Michel, MATRA Marconi Space, France; Desaint-vincent, Arnaud, MATRA Marconi Space, France; Lecouat, Francois, MATRA Marconi Space, France; AGARD, Knowledge-Based Functions in Aerospace Systems; Nov 1, 1995, 13 p; In English; See also 19960012290; Avail: CASI; A03, Hardcopy; A02, Microfiche

The first section of this paper outlines a baseline structure for knowledge-based guidance and control functions in the context of space missions. Guidance and control functions will be referred to here as 'Spacecraft Mission Operations', i.e., all the functions required to implement space missions. The development of a general baseline structure is difficult since these functions may vary considerably from manned space mission to unmanned mission, or from an earth observation satellite mission to a communications satellite mission. This section focuses on unmanned missions since they correspond to a majority of the actual space missions, and it presents a generic structure that is applicable to any kind of unmanned mission. Adaptation of this structure to manned space missions (e.g. Space Shuttles, Space Stations) is also discussed. The remaining section include 'New Challenges for Spacecraft Operations and KBS (Knowledge Based Systems) Applications', 'Procedures Preparation', 'Plan Generation', 'Operations Automation', 'Lessons Learned from the Deployment of OPSWARE(tm) Applications', and 'Major Stakes for the Coming Decade and Conclusions.'

In view of the importance of space capability to the fulfillment of future NATO requirements, the Flight Vehicle Integration Panel of AGARD has placed increased emphasis on space technology. The goal of the symposium reported in this document was to permit information exchange and discussion on the test aspects of space systems design and development with the emphasis on systems related to anticipated future capabilities and the importance of adequate testing, and continued with six sessions comprising 28 technical papers in all. These sessions focused on: Testing Requirements and Practices; Flight Dynamics and Flexible/Deployable Structures; Systems Development and Evaluation; Simulation; Space Flight Experiments; and Test Facilities and Support.

MIL-STD-1540 Test Requirements For Space Vehicles was first issued in 1974. This Military Standard prepared by The Aerospace Corporation for the USA Air Force space programs has been a reference for defining test programs for most U.S. DOD space systems. The third revision, to be MIL-STD-1540C, was prepared over the last two years with a primary objective of including test requirements for launch vehicles and upper stages. This paper discusses the background and effectiveness in using earlier revisions of the Standard and summarizes the major changes incorporated in MIL-STD-1540C 'Test Requirements for Launch, Upper Stages and Space Vehicles.'

This paper describes test programs that develop and qualify spacecraft deployable structures. Spacecraft deployable structures (examples are solar arrays, antennas and booms) are typically a combination of moving mechanical assemblies (examples are joints, latches and gimbals) and structural elements. Moving mechanical assemblies contain numerous potential sources of nonlinearities, such as freeplay, friction and hysteresis in joints and sliding surfaces. Also, larger deployables have low natural frequencies when deployed and may have large area to weight ratios. These subsystems can be significantly affected by gravity, air, humidity and other 'ground based effects'. This paper discusses how to address the concerns for deployable structures testing when simulating the desired environments and demonstrating functionality.

This paper describes the work performed at ULB for the development of active structures for space applications, using the piezoelectric technology. The control strategy involves two embedded control loops. The inner loop consists of a decentralized active damping using

colocated actuator-sensor pairs and control schemes with guaranteed stability properties. The outer loop consists of a pointing or position control using non-colocated actuators and sensors. Two examples of active damping are presented: a truss with linear actuators and a plate with piezo strips. Next, a position control is developed for the truss. The control law is derived from the frequency-shaped LQG methodology, using a simplified model of the actively damped structure; the bandwidth of the control system includes the first two flexible modes of the structure. It is demonstrated that the active damping improves substantially the performance and the robustness of the position control loop, inside and outside its bandwidth.

STRUCTURAL VERIFICATION OF THE SPACE STATION FREEDOM FORCE MOMENT SENSOR (FMS) USING FINITE ELEMENT MODELLING TECHNIQUES AND QUALIFICATION TESTING**

Christie, B., Canadian Astronautics Ltd., Canada; Mackay, B., Canadian Astronautics Ltd., Canada; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 11 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The design and development of the Canadian Force Moment Sensor (FMS) for use on the Space Station Remote Manipulator System (SSRMS) involved structural verification of strength, stiffness and life capabilities. The FMS, which is comprised of a primary structure - the sensor ring unit (SRU) and an electronics unit (EU), is used to detect on-orbit, operational forces and moments by measuring strain across six complexly shaped flexural members (struts). To achieve the required sensitivity, the struts must maintain a relatively high degree of flexibility which makes them more susceptible to the severe, repetitive loading environments experienced during the launch and on-orbit phases. The structural verification of the FMS system was demonstrated by structural analyses and qualification testing. The structural analyses included detailed finite element modelling of the FMS-SRU which examined strength margins, stiffness characteristics and fracture susceptibility. The Qualification Test Program supported the finite element modelling and included strength and stiffness testing using special test equipment (STE) in addition to the standard environmental tests. This paper describes the mathematical modelling and testing which was used to verify the structural performance of the FMS, and the techniques used in correlating test results with the predictions.

MASTERING THE EFFECT OF MICROVIBRATIONS ON THE PERFORMANCES OF RECONNAISSANCE SATELLITES**

Monteil, D., MATRA Marconi Space, France; Guillaud, V., MATRA Marconi Space, France; Laurens, PH., MATRA Marconi Space, France; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 11 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The development of very high resolution observation satellites has led to microdynamic problems. The quality of the images produced by reconnaissance satellites implies that they observe stringent line-of-sight stability requirements. The aims of this paper are to present the methodologies used at MATRA MARCONI SPACE (MMS) and to show the importance of tests in the prediction and verification logic. In the first part, stability requirements for reconnaissance satellites are reviewed. Constraints issued from new signal processing technologies are presented. In the second part, microvibration sources, their propagation throughout the satellite and their effects on the line-of-sight (LOS) are detailed. The prediction and verification logic is described in the third part. It is based on an intimate combination of analyses and tests at equipment, subsystem and satellite levels: the proposed approach for microdynamics is similar to thermal and mechanical processes using hierarchical specifications, tests, analyses, and interface control documents. Finally, several examples of

microdynamic tests performed at MMS on reconnaissance satellites are presented to illustrate their major contributions to high frequency pointing requirements demonstration.

AEROTHERMODYNAMIC TESTING REQUIREMENTS FOR FUTURE SPACE TRANSPORTATION SYSTEMS

Paulson, John W., Jr., NASA Langley Research Center, USA; Miller, Charles G., III, NASA Langley Research Center, USA; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 22 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Aerothermodynamics, encompassing aerodynamics, aerothermodynamics, and fluid dynamic and physical processes, is the genesis for the design and development of advanced space transportation vehicles. It provides crucial information to other disciplines involved in the development process such as structures, materials, propulsion, and avionics. Sources of aerothermodynamic information include ground-based facilities, computational fluid dynamic (CFD) and engineering computer codes, and flight experiments. Utilization of this triad is required to provide the optimum requirements while reducing undue design conservatism, risk, and cost. This paper discusses the role of ground-based facilities in the design of future space transportation system concepts. Testing methodology is addressed, including the iterative approach often required for the assessment and optimization of configurations from an aerothermodynamic perspective. The influence of vehicle shape and the transition from parametric studies for optimization to benchmark studies for final design and establishment of the flight data book is discussed. Future aerothermodynamic testing requirements including the need for new facilities are also presented.

The McDonnell Douglas Delta Clipper Team recently completed the initial flight testing of a one third scale version of an operational single stage to orbit vehicle. The Delta Clipper Experimental, DC-X, is a 14 m tall, totally reusable, liquid hydrogen/liquid oxygen fueled test vehicle powered by four P&W RL-10AS rocket engines. It has totally autonomous on board flight control and mission control systems; flight test mission requirements are simply added through software to the mission controller. The DC X is designed to explore and validate the low speed flight qualities of a vertical take-off and vertical landing spacecraft and its flight characteristics closely duplicate those predicted for the full scale DC-1 vehicle. The DC-1 vehicle would be capable of routinely flying people and/or cargo to and from space and would have a lift capacity for carrying 12 metric tons to low earth orbit.

FADS: A DEMONSTRATOR FOR MILCOMSAT AOCS

Huddleston, Martin, Defence Research Agency, UK; Cope, Paul, MATRA Marconi Space Portsmouth, UK; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 7 p; In English; See also 19960003881; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

This project covers the attitude and orbit control systems (AOCS) research program being carried out as part of the MOD applied

research program for AD CIS(OR)1. The project program is to evaluate the candidate sensor technologies and control algorithms, such as Kalman filters, which may be applied to future UK military ComSats. The specific needs of military satellites for robust and threat-resistant control are not offered by current civil technologies which normally use vulnerable earth sensors or RF pointing which is vulnerable to deception. The program is also to investigate ways of reducing control system complexity and improvements in attitude control precision by enabling structural modes to be controlled. The project examines the most promising attitude control system technologies required to support such future communications payloads. User requirements indicate a need for improved threat resistance and for narrower spot beams, and the program supports this perceived need by the use of improved sensors and control algorithms. Improved pointing on civil ComSats is normally by means of ground RF measurements to form a closed loop control system with the spacecraft. For threat reasons this method is unsuitable for military ComSats, and on-board sensors are therefore used. The use of Silicon array star or earth sensors are the most promising, and the sensor program is to concentrate on these. Limited development and available civil sensors will be considered. Experimental work is based on demonstrating and evaluating real hardware in-the-loop on an existing air bearing experimental rig. This offers the closest simulation of real flight performance that can be obtained. The program will develop the Filtered Attitude Determination System (FADS) rig to be fully representative of a MilSatCom satellite, threat-resistant AOCS solution, employing Silicon array star and earth sensors. Both the BAe Mosaic Earth Sensor (MES) and Marconi Versatile Star Sensor (VSS) technologies show considerable potential as attitude sensors. The VSS and MES capabilities will be evaluated on the FADS rig.

PEGASUS AIR-LAUNCHED SPACE BOOSTER FLIGHT TEST PROGRAM

Elias, Antonio L., Orbital Sciences Corp., USA; Knutson, Martin A., NASA Ames Research Center, USA; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 9 p; In English; See also 19960003881; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Pegasus is a satellite-launching space rocket dropped from a B52 carrier aircraft instead of launching vertically from a ground pad. Its three-year, privately-funded accelerated development was carried out under a demanding design-to-nonrecurring cost methodology, which imposed unique requirements on its flight test program, such as the decision not to drop an inert model from the carrier aircraft; the number and type of captive and free-flight tests; the extent of envelope exploration; and the decision to combine test and operational orbital flights. The authors believe that Pegasus may be the first vehicle where constraints in the number and type of flight tests to be carried out actually influenced the design of the vehicle. During the period November 1989 to February of 1990 a total of three captive flight tests were conducted, starting with a flutter clearing flight and culminating in a complete drop rehearsal. Starting on April 5, 1990, two combination test/operational flights were conducted. A unique aspect of the program was the degree of involvement of flight test personnel in the early design of the vehicle and, conversely, of the design team in flight testing and early flight operations. Various lessons learned as a result of this process are discussed throughout this paper.

USE OF SIMULATION TOOLS AND FACILITIES FOR RENDEZVOUS AND DOCKING MISSIONS

Serrano-Martinez, J. B., Universidad Politécnica de Madrid, Spain; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 12 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper presents a methodology for the use of simulation tools and facilities for the different phases of a Rendezvous Docking (RVD)

project. The methodology is developed trying to minimize development risks and planning shifts. Emphasis is placed on the elements which are unique on the RVD systems, namely, the Guidance, Navigation and Control subsystem, the on-board operations and the docking mechanism assembly. Such a methodology is based on the reuse of existing simulation tools and facilities in Europe. The Automatic Rendezvous Capture Demonstration Mission (ARC) is taken as example RVD project. The rationale of the proposed methodology presented including: the role of simulators during the different phases of the RVD project (namely, development, verification, execution, and post flight phases), the identification of simulation requirements derived from the foreseen application and the particularities of the RVD systems, the review of existing simulation tools and facilities in Europe and the analysis of their applicability for the ARC project including identification and analysis of the required upgrades and adaptations on the reused simulators and the required characteristics of the non-existing simulators.

Contemporary AOCS are equipped with local Attitude Control Computers which provide sophisticated Attitude and Orbit Control functions, automatic Failure Detection and Isolation functions and extensive Telemetry and Telecommand handling functions. Generic models of the design, development and test life cycle approaches for such intelligent AOCS are emerging. Also knowledge of the activities to be performed and the generic design, development and test environments to be used during the different phases is accumulating. Lessons learned can be used to improve AOCS development life cycle approaches and to define new development and test environments which improve the efficiency of the design, development and test life cycle and quality of the product. The SAX (Satellite per Astronomia a raggi X) satellite is equipped with a contemporary AOCS providing the above mentioned functions. In this paper the SAX AOCS software design, development and test life cycle is described as an example of AOCS software development. Lessons learned and suggestions for possible improvements are given.

NASA TECHNOLOGY FLIGHT EXPERIMENTS PROGRAM

Pruscha, Stephen L., Jet Propulsion Lab., California Inst. of Tech., USA; Levine, Jack, NASA Washington, USA; Russo, Samuel C., Hughes Aircraft Co., USA; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 9 p; In English; See also 19960003881; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

In addition to its scientific and life sciences experimental programs, NASA conducts flight experiments directed at development of space systems technologies. The experiments are conducted to obtain research data, to evaluate the performance or operation of experimental hardware in the space environment, or to validate components, subsystems, or systems prior to application in future spacecraft or missions. The requirements for specific technology experiments, and the priority assigned to them, vary significantly depending on the maturity of the technology. Some of the flight experiments address technologies still in the early research stage, while others are conducted to validate technology at relatively advanced levels of maturity. This paper discusses the overall technology flight

experiments program and reports in some detail on four current or recently flown experiments ranging from research to technology validation at the system prototype level.

Arcjet and ion propulsion offer potentially significant reductions in the mass of propulsion systems required for Earth orbiting satellites and planetary spacecraft. For this reason, they have been the subject of validation and demonstration programs. After examining the benefits of electric propulsion, this paper discusses the technology base for the Electric Propulsion Space Experiment (ESEX) arcjet demonstration experiment and the NASA Technology Application Readiness (NSTAR) ion propulsion validation program. As part of the Advanced Research Global Observation Spacecraft (ARGOS), ESEX will perform ten 15-min firings of a 30-kW ammonia arcjet. NASA's validation program, NSTAR, consists of two major elements: a ground-test element and an in-space experiment. The ground element will validate the life, integrability, and performance of low-power ion propulsion. The in-space element will demonstrate the feasibility of integrating and flying an ion propulsion system. The experiment will measure the interactions among the ion propulsion system, the host spacecraft, and the surrounding space plasma. It will provide a quantitative assessment of the ability of ground testing to replicate the in-space performance ion thrusters. By involving industry in NSTAR, a commercial source for this technology will be ensured. Furthermore, the successful completion of the NSTAR validation program will stimulate commercial and government (both civilian and military) uses of this technology.

SHUTTLE ORBITER EXPERIMENTS: USE OF AN OPERATIONAL VEHICLE FOR ADVANCEMENT AND VALIDATION OF SPACE SYSTEMS DESIGN TECHNOLOGIES

Holloway, Paul F., NASA Langley Research Center, USA; Throckmorton, David A., NASA Langley Research Center, USA; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 17 p; In English; See also 19960003881; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The NASA Orbiter Experiments (OEX) Program provided a mechanism for utilization of an operational space shuttle orbiter as a flight research vehicle, as an adjunct to its normal space transportation mission. OEX Program experiments were unique among orbiter payloads, as the research instrumentation for these experiments were carried as integral parts of the vehicle's structure, rather than being placed in the orbiter's payload bay as mission-unique cargo. On each of its first 17 flights, the Orbiter Columbia carried some type of research instrumentation. Various instrumentation systems were used to measure, in flight, the requisite parameters for determination of the orbiter aerodynamic characteristics over the entire entry flight regime and/or the aerodynamic-heating rates imposed upon the vehicle during the hypersonic portion of atmospheric entry. The data derived from this instrumentation represent benchmark hypersonic flight data heretofore unavailable for a lifting entry vehicle. The data are being used in a continual process of validation of state-of-the-art methods, both experimental and computational, for simulating/predicting the aerodynamic and aerothermal characteristics of advanced space transportation vehicles. This paper describes the OEX Program complement of research experiments, presents typical flight data obtained by these experiments, and demonstrates the utilization of these data for advancement and validation of vehicle aerothermodynamic-design tools. By example, the concept of instrumenting opera-

tional vehicles and/or spacecraft in order to perform advanced technology development and validation is demonstrated to be an effective and economical method for maturing space-systems design technologies.

EXTENSION OF THE ESA TEST CENTRE WITH HYDRA: A NEW TOOL FOR MECHANICAL TESTING

Brinkmann, Peter W., European Space Agency. European Space Research and Technology Center, Netherlands; AGARD, Space Systems Design and Development Testing; Mar 1, 1995, 10 p; In English; See also 19960003881; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The introduction outlines the verification concept for programs of the European Space Agency (ESA). The role of the agency in coordinating the activities of major European space test centers is summarized. Major test facilities of the environmental test center at ESTEC, the Space Research and Technology Centre of ESA, are shown and their specific characteristics are highlighted with special emphasis on the six-degree-of-freedom (6-DOF) hydraulic shaker. The specified performance characteristics for sine and transient tests are presented. Results of single-axis hardware tests and 6-DOF computer simulations are included.

A brief review of different measurement techniques for speed, pressure, and temperature on a re-entry vehicle is given in order to evaluate their applicability and limitations to the design of an air data system. A pressure-sensors based air data system is then assumed and an engineering aerodynamic model is used to investigate the influence of the measurement errors on the relevant air data parameters necessary for light guidance and control.

For military and civilian needs, satellites are becoming more and more autonomous, smart (i.e., including big integration devices) and capable (i.e. processing large quantities of broad bandwidth data). The technologies use to achieve such goals are sensitive to both noise and steady-state damage produced by the space environment. The purpose of this presentation is to describe some aspects of the problem, aiming at predicting overall system behavior in space. Indeed such a ground check of environmental hardness can be a daunting

task considering the complexity of the space threat and the understandable reluctance of project managers to subject all or large portions of their systems to extensive possibly destructive testing.

In session 4 we shall look at basic equations of motion of a capsule during its approach and entry and note some relationships between trajectory, vehicle parameters and structural and thermal loads in order to investigate which vehicle characteristics are important in capsule aerothermodynamic design. Typical entry scenarios are explained including orbital transfer, aerobraking, and aerocapture. Design considerations for a ballistic capsules are explored with reference to Mars, Titan and Earth return, while a lifting capsule trade-off is considered for Earth return.

AEROASSIST KEY TO RETURNING FROM SPACE AND THE CASE FOR AFE

Williams, Louis J., NASA, USA; Putnam, Terrill W., NASA, USA; Morris, Robert, NASA Marshall Space Flight Center, USA; May 1995; 32p; In English; See also 19970026365; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The Aeroassist Flight Experiment (AFE) is important in the development of a substantial and cost-competitive space industry. It is a research program to develop the technology base needed to design a new class of advanced entry vehicles that will play a key role in establishing a mature U.S. space presence in the next century. A dynamic and economical space program in the 21st century will include many operations involving the return of satellites, materials, and products from high Earth orbits (HEO), lunar bases, and planetary missions. The common and dominant characteristics of vehicles returning from such missions will be their very high speed as they approach the Earth. This high speed must be reduced substantially before the returning vehicle can be landed safely on Earth or placed in low Earth orbit (LEO), where the Space Shuttle operates now and the Space Station Freedom will operate in the future. LEO is a strategic that will always play a critical role in any space program. Its location just beyond earth's appreciable atmosphere can be reached from earth with the lowest cost in energy, and it is the natural and convenient spaceport location. In the next century LEO will contain a broad complex of assembly, research, repair, and production facilities. Their effective and cost-competitive use will require a class of routine workhorse transportation vehicles whose importance might be over-looked at a time when dramatic space exploration is occurring. Yet it is these vehicles, the Aeroassisted Space Transfer Vehicles (ASTV's) that will provide that solid transportation base on which a productive space industry will grow. The ASTV's will be assembled in orbit and will never return to earth's surface. They will be used to transfer people and material from high locations to LEO. They will reduce their high velocities in the outer reaches of the earth's atmosphere where aerodynamic drag will slow them to the appropriate speed for LEO. They will then maneuver out of the atmosphere and into a desired orbit. The present consensus is that this is the only cost-effective method of reducing the speed of such vehicles to the required level. The ASTV's will operate at very high altitudes where the atmosphere is exceptionally thin and the flight data need for their safe and efficient design are not adequately known. Much critical scientific research must be done to

build the technology base needed to make such a design. The research program discussed in this publication, the AFE, is specifically aimed at acquiring the knowledge for this technology base.

Since 1977, ONERA has ground and flight tested different techniques for heat-shield recession: acoustic and combined temperature/ablation optical measurements. This last technique uses a gage that views the radiation optically from a cavity embedded within the heat shield. Flight measurements, both of temperature and of passage of the ablation front, are compared with data generated by a predictive numerical code. The ablation and the heat diffusion into the instrumented ablator can be simulated numerically to evaluate accurately the errors due to the presence of the gage. The ablation measurement alone of the reentry body nose is made by an acoustic gage. The temperature measurement alone of the heat shield inner wall will be soon carried out by an optical sensor.

The SEP (European Company of Propulsion) developed a testing facility making it possible to carry out the acceptance tests of engines SPT 100 and the tests of development of an engine of second generation SPT MK 2. This installation results from the modification of an existing vacuum chamber. It is fitted with a cryogenic pump of great capacity making it possible to pump Xenon effectively, of a balance of measurement of pushed and an automatic system of control of test. The results obtained are compared favorably with those recorded on bulkier installations with the USA and in Russia.

The development of solid propellants is a major topic at the institute. For the purpose of getting more insight into the combustion behaviour of solid propellants and the exhaust plume signatures of rocket motors some new spectroscopic and pyrometric devices were developed. In the UV-VIS-region an Optical Multichannel Analyzer (OMA) is used. For the detection of radiation in the IR-region three systems are available ranging from 1.2 to 14.5 micron with a wavelength resolution of about 1 percent and a scanning rate of 10 ms per spectrum. The time resolution of the two color pyrometer ranges from DC up to 50 kHz and detects fast particles with temperatures above 1000 K. In this paper these methods of investigation are described and illustrated in different applications.

DEMILITARIZATION OF LANCE ROCKET MOTORS

Sargent, Peter, British Aerospace Defence Ltd., UK; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995; 6 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

In 1992 Royal Ordnance was awarded contract by NAMSAs for the demilitarization of NATO's European stock of Lance missile rocket motors. Lance is a liquid fueled surface to surface guided missile designed to give general battlefield support with either a nuclear or conventional capability at ranges of up to 130 km. The NAMSAs contract required Royal Ordnance to undertake the following: (1) transportation of missiles from NATO depots in Europe to Royal Ordnance's factory at Bishopton in Scotland; (2) establishment of a dedicated demilitarization facility at Bishopton; and (3) demilitarization of live M5 and M6 training missiles by the end of 1994.

A three dimensional finite element analysis and a one dimensional incompressible flow model were used to investigate the interaction between the internal ballistics and the structural grain deformations for the Sparrow Mark 52 rocket motor. The results confirm earlier investigators' conclusions (based on two dimensional structural analysis) that a mechanism exists for pressure spiking driven by choking of the gas flow within the bore cavity due to grain structural deformations. Significant differences were found between the 2D and 3D results, however, the 3D analysis requires a higher propellant modulus to prevent choking under the same analysis conditions.

23 CHEMISTRY AND MATERIALS (GENERAL)

Sustained high speed flight requires the highest levels of propulsive and aerodynamic performance. One of the highest performance classes of propulsion system envisioned is the air augmented rocket. The potential for significant Imp increases to be gained using an air augmented rocket (with either liquid, solid or hybrid propellant boost propulsion systems) has long been recognized. Using intake air as the primary oxidizer with rocket fuel significantly reduces on-board propellant mass, vehicle mass and volume for the same total impulse delivered compared to conventional chemical rockets. The list of technical challenges for viability and use include: (1) Booster configuration including integrated (boost propellant inside air-augmented combustion chamber, with or without a typical rocket nozzle), parallel or tandem boosters, and propellant combination drives booster complexity, need for ejecta, boost system ballistic requirements, air-augmented rocket performance and vehicle aerodynamics; (2) Complexity of starting flow through the inlets and initiating efficient air-augmented ignition; and (3) Aerodynamics involved in starting and unstaring inlets in supersonic flow while performing high angle of attack maneuvers can negatively impact missile performance.

Solid propellant rocket motors and gas generators are used in military and civil devices. Missiles, boosters, space propulsion, pyrotechnic actuators are examples. The structural capability of the grain over time and under varying temperature, humidity, and mechanical loads, is of prime concern for the reliability, safety and service life of the device. From 1994 to 1996 an AGARD working group has collected, reviewed and evaluated the methods used for structural analysis of solid propellant grains within the NATO nations and has issued an advisory report consisting of 8 chapters: (1) Overview of Solid Propellant Rocket Motor Design; (2) Application of Structural Integrity Assessment; (3) Structural Analysis; (4) Material Characterization; (5) Failure Criteria; (6) Margin of Safety Determination; (7) Verification; and (8) Recommendations and Conclusions. Standardization and preferable approaches are recommended.

APPLICATION OF LASER-INDUCED FLUORESCENCE (LIF) TO LIQUID-PROPELLANT ROCKET ENGINE TESTING

Brasier, C. W., Sverdrup Technology, Inc., USA; Drakes, J. A., Sverdrup Technology, Inc., USA; Simmons, M. A., Sverdrup Technology, Inc., USA; May 1998; 10p; In English; See also 19980206002; Original contains color illustrations; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Combustion exhausts present a challenging problem for researchers due to the extremely harsh environment, and nonintrusive diagnostics are often sought to provide flow property information. Laser-induced fluorescence (LIF) is one technique in which a chosen flow molecule or marker is probed to yield gross flow properties, such as static temperature and flow velocities. The work presented herein describes the application of LIF to the combustion exhausts of several full-scale liquid-propellant rocket engines spanning a wide range of operational parameters. The method is based upon the use of cw ring-dye lasers which scan in frequency over either the Na D1 or D2 line at 5896 and 5890 Å. Na is used as a basis for this approach since it occurs as a trace element in both hydrogen and amine rocket fuels. The generic apparatus is described, including a discussion of the collection and interpretation of the LIF signal to yield radial and temporal profiles of radial flow velocity, static temperature, and fuel

distribution. It was found that the LIF technique provides quality data in most cases. Certain stressing situations were also found in which data on the flow properties were not obtainable. Also, computational fluid dynamics (CFD) modeling of the plumes was used to provide baseline estimates of the exhaust flow properties. The model reasonably predicted the gross behavior of the flow as determined by the LIF technique, although some items of fine spatial structure were not reproduced very well.

Tactical missiles based on Pulse Detonation Wave Engines (PDEs) have the potential of increased range, enhanced survivability, lower cost, and reduced time of flight. The advantages derive from two overall features of the intermittent combustion device compared to competing steady flow engines. The first feature is the quasi-constant volume characteristic of the detonative combustion process with theoretical increases of the specific impulse and the thermodynamic cycle efficiency. The second feature is related to a simple design which combines compression, combustion, and thrust production in one component. The paper discusses various missile applications of the detonation based cycle, several design issues, and R&D needs which have to be resolved to take full advantage of the PDE.

Report No.(s): AGARD-LS-205; ISBN 92-836-1042-3; Copyright Waived; Avail: CASI; A08, Hardcopy; A02, Microfiche

Smart materials and structures technology is the integration of sensing and actuation elements into a structure or even more ambitiously into a material, with sensor and actuator being linked by a controller. Materials actually favored for integration include optical fibers and piezoelectric materials with respect to sensors, piezoelectric and electrostrictive materials, shape memory alloys or electro-rheological fluids with respect to actuators and microprocessors, neural networks, fuzzy logic and various types of signal processing with respect to control. The first part of the lecture series is mainly focussed on understanding the fundamentals of smart materials and structures technology and achieving the capability to judge the use of that technology with respect to individual applications. Presentations related to sensor and actuator materials, mechanics of smart structures, control and data processing, as well as structural integration of sensors, actuators, and generally electronics are therefore the focus of this part. In a second part, applications of smart structures technology are considered with respect to aircraft. Topics to be

covered include monitoring the health/damage of aircraft structures or components, conceptual design of an adaptive wing, and electromagnetic antennae and their structural integration.

COMPOSITE MATERIALS

19950017082 Virginia Univ., Center for Electrochemical Science and Engineering., Charlottesville, VA, United States

THE DETECTION AND ANALYSIS OF GALVANIC DAMAGE IN BMI/GRAPHITE FIBER COMPOSITES

Taylor, S. R., Virginia Univ., USA; Cahen, G. L., Jr., Virginia Univ., USA; AGARD, Corrosion Detection and Management of Advanced Airframe Materials; Jan 1, 1995, 12 p; In English; See also 19950017076; Sponsored by Virginia Center for Innovative Technology and Naval Air Warfare Center; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The use of graphite fiber polymer matrix composites (GFPMC) in multi-material assemblies which must maintain mechanical integrity in aqueous environments has focused attention on the galvanic degradation of these materials. of recent concern to the aerospace industry is the galvanic degradation of bismaleimide (BMI)-graphite fiber (GF) composites when galvanically coupled to an active metal (e.g. aluminum). A detailed understanding of the damage process, both in terms of mechanism and extent, has not been possible because of the lack of sensitive method to detect, quantify, and characterize damage in this material system. This study has used electro-chemical impedance spectroscopy (EIS) to monitor material interfacial changes in an 8-ply, 0 deg, unidirectional BMI-GF composite subjected to cathodic and anodic polarization in NaCl solutions, exposure to caustic solutions, and galvanic coupling to a series of metals (Al, Fe, Cu, Ti) in NaCl solutions. Cathodic polarization was found to produce porous electrode behavior which was attributed to breakdown of the fiber/matrix interface and subsequent moisture ingress. This is in contrast to caustic exposure which did not show a porous electrode response, presumably due to general BMI solvation. These electrochemical results in combination with mechanical shear tests performed in an array of chemical and electrochemical conditions indicate that long-lived reaction intermediates, e.g. peroxide and superoxide radicals, generated during the oxygen reduction reaction on graphite, not hydroxyl ions, are the key damaging species. This will have important implications to the development of more damage resistant polymer chemistries. The sensitivity of EIS has also indicated that couples to titanium, proposed to be a benign couple, caused changes in the impedance spectra similar to those for low cathodic overpotentials. The long term implications of these latter changes on composite durability are not known at this time, but warrant further evaluation.

This lecture series presents and discusses the scientific problem of advanced polymer and metallic composite materials for aerospace structures, strength optimization of composite structures, and their certification. Some challenges of using composite structures, including airframe concept definition, are studied. Fiber orientation

optimization principles for composite panels and shells are outlined. Procedures for certification of assemblies made out of composites are dealt with. Certification requirements, including requirements to estimate static and fatigue strengths, are formulated. Design conditions for composite structures are analyzed, including development.

A general discussion of the application of composite materials to airframes is presented. An overview of mechanical properties and the effect of layup is given. Factors that weaken the structure, including scatter in mechanical properties, the sensitivity of structural characteristics to environmental attack and length of service, and brittleness and the related sensitivity to stress concentration and impacts, are outlined. Polymer matrix composites are then compared to metal matrix composites. The paper concludes with a look at future generations of polymer matrix composites.

Considered are issues related to improvement of properties, fabrication and use of polymer matrix composites (PMCs) based on graphite, organic, and glass fibers for aerospace industries of Russia and other countries of the CIS. The best effect is shown to be attained when a partial involvement of these materials (for making certain structures) is transformed into 'global' design of large structures out of the PMCs.

The paper considers issues for the near future in the development of polymer matrix composites, including (1) effective use of nano-components and nano-level manufacturing processes for upgrading the physical (and mechanical) characteristics of composites; and (2) methods of development of 'smart' materials on the basis of functional components. The preparation of advanced thermosetting plastics that can be utilized as ready materials and matrices is described. The paper discusses the ability to predict the strengths of composites with nano-level components in which the strength, volume fractions, and spatial arrangement turn out to be interrelated.

The rate of polymer matrix composites (PMCs) replacing metals depends on development of PMCs with necessary characteristics, availability of manufacturing facilities and high-rate manufacturing processes, and effective methods and technologies for designing and testing the composite structures. In order to substantiate selection of reasonable methods for ensuring safety and reliability of composite airframes made out of PMCs, the paper addresses (1) the experience in fulfilling airframe service life requirements and (2) information on in-service damage of composite structures. Limitations on the use of PMCs in primary structures include brittle fracture, environmental attack, scatter of mechanical characteristics, and the influence on PMC efficiency of methods adopted for ensuring airframe safety. Aspects of damage to PMCs, in particular damage in production, in-service damage, and models and characteristics of brittle fracture resistance, are discussed.

Increasing the safety and service reliability of engineering structures made out of polymer matrix composites (PMCs) is a very challenging technical and economical problem. The structural and technological measures of providing service life of PMC aircraft structures are realized and verified while providing and improving the survivability through the following: (1) definition of PMC aircraft structure damages during manufacturing and service, (2) analysis of general and local stress-strain state of regular and nonregular structural zones, (3) prediction of the damage size growth and residual strength of PMC aircraft structures using the data of the damages and stresses in elements and joints, (4) determination of survivability based on probabilistic methods of predicting the failure of damaged PMC aircraft structures, (5) testing of structural schemes during preliminary and detailed design, and (6) full-scale static and fatigue laboratory tests of damaged PMC aircraft structures. A probabilistic model of failure is presented that accounts for a combination of structural, technological,

and service aspects; the stochastic nature of service loads and mechanical impacts; and the scatter of damage or defect sizes and failure resistance characteristics of polymer composites.

This report presents the scientific problem of composite structure optimization and certification. The approach to optimization of a lifting surface (a wing and empennage) is studied. The use of arbitrary anisotropic models in the design process is shown. Some examples of designing composite structures are included. Certification problems are briefly considered including the design conditions and means of compliance.

CERTIFICATION OF PREFORMS AND STRUCTURE ELEMENTS
OF COMPOSITE MATERIALS**

Trunin, Yuri P., Central Aerohydrodynamics Inst., Russia; Advanced Polymeric & Metallic Composite Materials for Space and Aerospace Vehicle Structures and Strength Optimization of Composite Structures and their Certification; DEC. 1995, 7-1 - 7-13; In English; See also 19960020341; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The cost-efficient approach for certification of preforms and elements of composite materials is presented. The criterion of certification is the requirements that A- or B-values of a characteristic concerned are not less than the design values for a typical zone considered. The most critical typical zones are the ones with manufacturing defects, in-service impact damages, and structural stress risers. Unlike the usual guidelines our method does not require testing specimens from all of the general population. The approach relies on static and fatigue tests of specimens from one material batch which has the worst average properties. As the worst material batch it is suggested to consider that which will be produced with critical per ply thickness from the allowable range of per ply thickness alteration. The A- or B-values may be determined on the basis of experiment and/or analysis in consideration of environmental effect. The experimental and analysis substantiations of the suggested approach are presented.

An efficient procedure for certification of composite structures is developed in accordance with which for calculating basic values of mechanical and fatigue properties it is enough to obtain test results for the objects certified in one batch only. The procedure is based on the probabilistic model, formed as summary of extensive experimental investigations of strength and fatigue properties for composite materials, preforms, and elements made of them. Estimation error for basic

values according to the proposed procedure does not exceed 5% when scatter values of strength and fatigue properties are typical for composite materials.

The variation of properties of composite materials subjected to environmental attack and a method to evaluate these environmental effects are considered. Airframes, while in long-term service and/or storage, experience adverse temperature/humidity combinations which usually change the mechanical properties governing the material limits. The moisture absorbed decreases strengths and stiffnesses, thus increasing in-service deformation. Elevated temperatures intensify moisture absorption. Fibers are less sensitive to moisture than polymer matrices; therefore the moisture content may severely influence properties defined by the matrix strength, i.e., the compressive and shear stress limits. The impact of the in-service environment on the static, fatigue, and residual strengths (and stiffnesses) of full-size structural elements can be tested by a program which incorporates the maximum temperature likely to occur in service, the minimum temperature defined by the basic conditions and/or long flights at high altitudes, extreme accumulation of moisture, and dwelling of the structure in severe environment during the service life.

19960021135 NYMA, Inc., Cleveland, OH United States A SUMMARY OF DAMAGE MECHANISMS AND MECHANICAL PROPERTY DEGRADATION IN TITANIUM MATRIX COMPOSITES SUBJECTED TO TMF LOADINGS

Castelli, Michael G., NYMA, Inc., USA; Thermal Mechanical Fatigue of Aircraft Engine Materials; Mar. 1996; 12p; In English; See also 19960021124; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

An overview of thermomechanical fatigue (TMF) deformation, damage progression, and life is presented for multiple laminates of continuous SiC fiber reinforced titanium matrix composites (TMC's). Fundamental behaviors resulting from in-phase (IP) and out-of-phase (OP) TMF loadings are addressed with particular emphasis on the micromechanical damage mechanisms leading to macroscopic failure. This is accomplished through detailed microstructural examinations using both fractography and metallography. Further, macroscopic measures of damage progression based on mechanical property degradation are examined through data collected using an advanced TMF test technique which allows explicit measurements of the macroscopic (1) isothermal static moduli and (2) coefficient of thermal expansion (CTE) as functions of the TMF cycles. Zero-tension TMF life results indicate analogous trends for both (0) and (0/90) TMC laminates. High stress IP TMF and mid to low stress OP TMF loadings are life-limiting in comparison to maximum temperature isothermal conditions. Dominant damage mechanisms changed with cycle type. Damage resulting from IP TMF conditions produces measurable decreases in static moduli but only minimal changes in CTE occur. Microstructural damage is dominated by extensive (0) fiber cracking with sparse matrix damage and no surface initiated cracking. Under OP TMF conditions, notable static moduli and CTE degradations are experienced. Here, conditions promote environment enhanced surface initiated cracking. The (0/90) TMC also exhibits matrix cracking initiated at debonded (90) fiber/matrix interfaces. Both laminates show little to no (0) fiber cracking. Zero-tension TMF of a (90) TMC reveals significant changes in both the static moduli and CTE under IP and OP conditions. Mechanical property degradation patterns are very similar to those exhibited under isothermal loadings. Further, damage mechanisms promoted by isothermal, IP TMF and

OP TMF loadings are essentially identical, consisting of debonding at the fiber/matrix interface followed by matrix cracking which initiates at the debond and propagates transverse to the applied load.

19960021136 Naval Air Warfare Center, Aircraft Div., Patuxent River, MD United States TMF RESPONSE OF Ti-48Al-2V ALLOY AND ITS COMPOSITE

Lee, E. U., Naval Air Warfare Center, USA; Thermal Mechanical Fatigue of Aircraft Engine Materials; Mar. 1996; 14p; In English; See also 19960021124; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The fatigue behavior of a Ti-48Al-2V alloy and its composite, reinforced with particulate TiB₂, was investigated under in-phase thermal-mechanical cycling and isothermal cycling. In the thermal-mechanical fatigue (TMF) tests, the temperature was cycled between a minimum temperature T(sub min), 100 C, and a maximum temperature T(sub max) ranging from 750 C to 1400 C; the cyclic stress ranges were 2.8 - 28 MPa and 4.2 - 42 MPa. Employing the identical cyclic stress ranges, isothermal fatigue (IF) tests were conducted at a T(sub max). The lower the T(sub max) and the smaller the stress range, the longer was the TMF and IF lives for the Ti-48Al-2V alloy and its composite. IF inflicted damage earlier than TMF in the Ti-48Al-2V alloy, whereas their damaging effects were similar in the composite. Both materials had similar TMF resistance, but the composite showed greater IF resistance than Ti-48Al-2V alloy. The TMF mechanism is nucleation and growth of voids in interlamellar plate, twin and grain boundaries, their linkage, intergranular separation, and disintegration of lamellar structure.

Development in disciplines such as sensing technology, computation, control, micromechanics, materials including processing and many others has made significant progress during the past decades. This progress has been mainly possible through an in-depth analysis of the different aspects in these disciplines. To consequently take more advantage of this progress a synergy between these different disciplines has to be established, resulting in what has been termed to be smart materials and structures. Smart (alternatively active, adaptive, multifunctional or intelligent) materials and structures is - briefly explained - the integration of sensing and actuation elements into a structure or even more ambitiously into a material, with sensor and actuator being linked by a controller. Materials actually favored for integration include optical fibers and piezoelectric materials with respect to sensors, piezoelectric/electrostrictive materials, shape memory alloys and electro-rheological fluids with respect to actuators and microprocessors, neural networks, fuzzy logic and various types of signal processing with respect to control. Since performance of military aircraft and spacecraft has progressed in a sequence of steps in the past, smart materials and structures technology can thus be considered to be a next step in enhancement.

Smart materials are revolutionary new engineering materials/intelligent structures that sense and respond to their environment.

24 COMPOSITE MATERIALS

Emerging concepts for mission adaptable wings, helicopter blades and the active suppression of submarine noise are reviewed and used to identify the important basic elements of these intelligent structures. The fundamental principles of the main sensing approaches (based on piezoelectric, fiber optic, luminescent and other phenomena) are described together with the physical principles underlying approaches to actuation (piezoelectric/ electrostrictive materials, magnetostriction, shape memory alloys and electrorheological fluids). The best methods for design and processing of affordable smart materials are only beginning to be addressed by researchers; concurrent engineering and intelligent processing of materials concepts will be essential to transition smart materials from the laboratory into applications.

BOLTED JOINTS IN COMPOSITE STRUCTURES: AN OVERVIEW
Oplinger, D. W., Hughes Technical Center, USA; AGARD Conference Proceeding: Bolted/Bonded Joints in Polymeric Composites; Jan. 1997; 12p; In English; See also 19970019652; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Investigations of bolted joints from the introduction of advanced composites in the mid-to-late 1960's to the present are reviewed. Numerous efforts aimed at applying two dimensional elastic stress analysis in conjunction with appropriate testing have been conducted. Modelling of the pinplate contact problem by a radial displacement condition rather than a radial pressure distribution is physically more realistic and has been done in a number of efforts, starting with that of Oplinger and Gandhi in the early 1970's. However in the case of the problem of bearing-bypass stress interaction which is in principle controlled by the radial displacement description of the contact problem, a number of efforts have provided useful results, especially in conjunction with adjustments based on test data by superposition of the half-cosine radial pressure distribution for pure bolt bearing load and the open-hole plate solution for bypass load. Approaches to predicting failure using results of 2-D elasticity analysis are discussed. In addition, recent effort addressing bearing failure on the basis of the three dimensional stress state is considered. Currently, the details of the three-dimensional contact problem associated with bending deflections of the fastener as well as the interaction of the fastener head with the surfaces of the joint plate elements are seen to need additional study.

Graphite fiber reinforced polymeric composites have been used extensively in the primary and secondary structures of modern military and civilian aircraft. In these structures, bolted joints are important considerations in structural design and repair. Reviews of the literature indicated that most of the current design methods were developed for single fastener joints and, in general, design optimization, three dimensional effects and fatigue behaviour required further research and development. This paper reviews the results of the bolted joint technology development project sponsored by the Institute for Aerospace Research and the Canadian Department of National Defence. The project includes the development of computer-aided design tools for optimizing the design of multi-fastener composite joints and for predicting the fatigue behavior of pin/bolt loaded composite laminates.

Current focus and future direction of the development of analytical tools for repair of composite structures and other applications are presented.

The use of structural adhesives in engineering applications can offer substantial benefits in comparison to more traditional joining techniques such as mechanical fastening and welding. These include: Improved fatigue performance; ability to join dissimilar materials; ability to join thin gauge materials and honeycomb constructions; and simpler and cheaper component construction. Operational benefits which can result from the significant use of bonding include improved equipment performance, resulting largely from the significant weight reductions which adhesive bonding can provide, together with substantial reductions in both procurement and life-cycle maintenance costs. In particular, the use of adhesive bonding in the construction of advanced lightweight composite structures will be of major importance since mechanical fastening would impose penalties in terms of mechanical integrity and weight.

19970019665 Politecnico di Milano, Dept. di Ingegneria Aerospaziale, Milan, Italy

HYGROTHERMAL FATIGUE OF COMPOSITE BONDED JOINTS

Giavotto, V., Politecnico di Milano, Italy; Caprile, C., Politecnico di Milano, Italy; Sala, G., Politecnico di Milano, Italy; Jan. 1997; 10p; In English; See also 19970019652; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Adhesive bonding is the optimal technique to join composite laminates, because it does not induce stress concentrations, fibres cutting, resin delaminations and problems due to electrochemical non-compatibility. Notwithstanding, in many cases bolted and riveted joints have to be used, mainly in hot-wet environmental conditions, as well as when composites have to face chemically aggressive fluids, as hydraulic and de-icing fluids, oils and fuels. Moreover, the influence exerted on bonded joints by technological defects (voids, inclusions) and barely visible damages (due to low-energy impacts) should be addressed. The results of a research on the fatigue behaviour of wet-conditioned, impacted and defective composite bonded joints are reported. Single and double lap geometry carbon fabric/epoxy joints are considered, bonded with high-toughness adhesive. The specimens were wet-conditioned in hot water (70 °C) up to saturation. Barely visible damages were produced in the bonded region (influencing both the composite adherents and the adhesive layer) by means of low-energy impacts (0.5 J per mm laminate thickness) imparted by a spring-propelled horizontal apparatus with 20 mm hemispherical steel impactor). Defective bondings were simulated by including copper inserts, located in different positions. Defective, impacted and wet conditioned specimens were subjected to static and constant ampli-

tude fatigue testing (tension-compression, $R=-1$, 6Hz frequency); their performances were compared to the behaviour of plain specimens. The stiffness decrease and the damage growth were continuously monitored during the testing by means of extensometers and NDI techniques (ultrasonic scanning and dye penetrant radiography). The results consist in the comparison of the static stress-strain curves relevant to plain, defective, impacted and wet-conditioned specimens, the curves of stiffness decrease vs. number of cycles and the Woehler curves. Finally, the static characteristics and the fatigue performances are correlated with the damage growth and the adhesive progressive degeneration by analysing the radiographs and the SEM micrographs of the failed bonded region, in order to propose an interpretative model.

Current industry practice separates the design of an air vehicle's propulsion system from the design of its airframe. This practice causes many problems and inefficiencies particularly for advanced exhaust nozzle designs. It results in redundant aircraft structure to be insulated and shielded from the engine thermal and acoustic emanations. Perhaps, most importantly, it causes buckling and cracking at the joint interfaces where the thermally induced stresses are reacted. The critical joint interfaces are the co-cured/bonded joints between layers of dissimilar materials and the mechanical joints between structural components. Northrop Grumman's concept is to modernize the design, analysis, and construction of future high performance aircraft by integrating the exhaust nozzle/ exhaust washed structural components into the primary airframe structure through a combination of organic and ceramic matrix composite materials. Designing bolted and bonded joints to carry induced loads efficiently, then, is critical to an integrated structural approach. Northrop Grumman has evolved a variety of approaches to transfer loads, including co-bonding of dissimilar materials and unique joint designs. Ceramic matrix composite/ AFR700B bolted and bonded joints have been identified as a critical need, and under Air Force-contracted research, joints have been designed and analyzed and will be fabricated. Sub-element testing, including static and fatigue, will validate the design and analytical methodologies. Durability and maintainability will be validated through testing and nondestructive evaluation. Trade-off analysis performed on the bolted and bonded joints will address structural efficiency, reliability, supportability, and battle damage tolerance.

3-D COMPOSITES IN PRIMARY AIRCRAFT STRUCTURE JOINTS

Bersuch, Larry, Lockheed Martin Tactical Aircraft Systems, USA; Hunten, Keith, Lockheed Martin Tactical Aircraft Systems, USA; Baron, Bill, Wright Lab., USA; Tuss, James, Wright Lab., USA; Jan. 1997; 10p; In English; See also 19970019652; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Three-dimensional woven and braided inserts and preforms, when cocured into primary wing and fuselage laminate structure, offer reduced weight, increased performance, lower costs, and improved damage tolerance and ballistic survivability for future aircraft. To achieve these benefits, three-dimensional (3-D) weaving and braiding technologies must be characterized through the development of design criteria, design methods, structural concepts, and manufacturing processes. In addition to 3-D weaving and braiding, z-direction

reinforcement can be achieved through in-process fiber insertion with processes such as z-spiking, stitching, and short fiber additions to adhesives. Innovative applications of these technologies, combined with net shape curing processes such as resin transfer molding (RTM), electron beam cure, diaphragm forming, fiber placement, and curing, will result in the elimination of machined metal load fittings, fasteners, and reduction in weight at composite joints on future aircraft. Wing applications for 3-D composites would be at the intersection of spars and ribs and in the radius area between spars/ribs and the lower skin of a cocured wing assembly. In fuselage structure, 3-D composites eliminate the need for machined fittings and fasteners at concentrated load joints such as those at inlet duct, weapons bay, gun-trough, and fuel floor intersections with bulkheads/frames. This paper is directed at design for manufacturing of 3-D composite structures to best exploit the structural properties that they exhibit.

Z-FIBER TECHNOLOGY AND PRODUCTS FOR ENHANCING COMPOSITE DESIGN

Freitas, G., Aztex, Inc., USA; Fusco, T., Aztex, Inc., USA; Campbell, T., Foster-Miller Associates, Inc., USA; Harris, J., Foster-Miller Associates, Inc., USA; Rosenberg, S., Foster-Miller Associates, Inc., USA; Jan. 1997; 8p; In English; See also 19970019652; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Z-Fiber(TM) technology uses small, solid, cylindrical pins to greatly enhance the performance of composite structures. These pins, typically 0.25 to 0.50 mm in diameter, can be used for many structural applications. Z-Fibers, either composite or metal, are inserted through the thickness of a composite laminate to increase out-of-plane strength, damage resistance, and through thickness thermal conductivity. Z-Fiber is also used for structural joints and can be designed to be the structural network of the core material in an extremely weight and cost efficient sandwich structure. Z-Fiber technology has been under development for over ten years. The growth of this technology, originally developed by Foster-Miller Inc., has begun to move at a very accelerated rate under Aztex Inc. during the past two years. Despite this extended development period, the revolutionary advances in the performance of composite structures made possible by this technology are only now becoming fully apparent. When used at the conceptual stage of aircraft design, when the overall structural arrangement is being formulated, Z-Fiber technology can completely change the current design approaches. This paper presents a general overview of Z-Fiber technology and products and focuses on the work to date to form structural joints. The paper demonstrates, even at this early stage of development, Z-Fiber's capability to outperform fasteners and significantly increase the static survivability of composites.

Hypersonic flight constitutes for materials developers a big challenge considering the requirements they have to be compliant with. The mastering of this key technology is necessary to design hypersonic vehicle as they are needed to realize the thermal protection system as well as some parts of engines. The requirements can be identified ranking in three categories which are technical, industrial feasibility and producing costs. These three topics will be discussed in this paper. For the thermal protection system of reentry vehicles, carbon/carbon composites protected against oxidation as well as carbon/silicon carbide composites have already demonstrate they are good candidates to sustain high thermomechanical loads. But in order to be compliant with development costs of future system an effort has to be performed in simplified designs. For future engines as scramjet requirements are much more severe but a first demonstration of appli-

25 INORGANIC AND PHYSICAL CHEMISTRY

cability of such materials has been performed on an injection strut. Nevertheless the demonstration of behaviour of the coatings to combustion ambiances has yet to be demonstrated for long term and reusable applications.

THE USE OF ELECTROCHEMICAL IMPEDANCE SPECTROSCOPY TO PREDICT THE CORROSION OF ALUMINUM-LITHIUM ALLOYS IN MARINE ENVIRONMENTS

Lenard, D. R., Defence Research Establishment Pacific, Canada; Moores, J. G., Defence Research Establishment Pacific, Canada; Roberge, P. R., Royal Military Coll. of Canada, Canada; Halliop, E., Royal Military Coll. of Canada, Canada; AGARD, Corrosion Detection and Management of Advanced Airframe Materials; Jan 1, 1995, 12 p; In English; See also 19950017076; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

In order to acquire some experience with the behavior of aluminum-lithium alloys in the marine environment, the Defense Research Establishment Pacific compared panels made from Aluminum Alloy (AA) 2090 and 8090 sheet with the conventional alloys AA 7075 and 2024, respectively, in several tests involving long term exposure to sea water fog and full or partial immersion in sea water. The results of these were then compared with the results of a new technique, developed by the Royal Military College of Canada for the analysis of electrochemical impedance measurements, that was performed on these alloys in simulated sea water. The long term exposure tests indicated that corrosion problems could occur with aluminum-lithium alloys in the marine environment. The 8090 alloy was found to suffer from severe localized attack, including intergranular cracking, along edges that were immersed in sea water. The 2090 alloy, however, appeared to offer some advantages over its 7075-T6 counterpart, as it was more resistant to corrosion at its edges, even though it suffered as much or more corrosion on the rolled surfaces. On some 2090 panels, the corrosion resistance of the edges was found to be enhanced by cold work associated with shearing. Polarization resistance measurements were generally consistent with the results of the long term exposure tests, although they predicted corrosion rates for the rolled surfaces of the 8090 and 7075 alloys that were apparently too high. The angle of depression of the Nyquist plots appeared to correlate with the number of corrosion sites within a given area and was in good agreement with visual observations of the long term exposure panels.

19960008957 Delegation Generale de l'Armement, Bourges, France CHARACTERIZATION OF THE HEAT FLUX AND ESTIMATE OF THE RISKS OF BURNS AROUND THE ENGINES AT VERY SHORT TIME OF COMBUSTION CARACTERISATION DU FLUX THERMIQUE ET ESTIMATION DES RISQUES DE BRULURES AUTOUR DES MOTEURS A TRES COURT TEMPS DE COMBUSTION

Franco, P., Delegation Generale de l'Armement, France; Balageas, D., Delegation Generale de l'Armement, France; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 8 p; In French; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The heat flux around the engines of missiles or rockets is related to the ejection of a large quantity of hot gases during the shooting and can constitute an important harmful effect. In addition to the risks of ignition of the immediate environment (vegetation), these effects can involve risks of burns. In order to better take into account these effects,

a study was undertaken in order to develop estimated tool risks of burns during a very short operating time of combustion. Thus, a methodology of characterization of the heat flux in the jet of the engines was studied. It was elaborate in order to take account of following specificities: very short response times due to the speed of the phenomena; mechanical resistance to projections of unburnt residues in the jet; representativeness of the heat fluxes in the skin; and distinction between flows - convective and radiative. In complement, a thermal model of the skin was studied. It is based on the model of skin of Stolwijk and Hardy and allows the calculation of the profile of temperature in the various layers of the skin: subcutaneous skin and fabrics. A law of destruction of the cells according to the temperature was derived from work of Henriques and Stoll and was adapted. This tool allows the forecast of the risks of burns around the engines; it can be used, in particular, to delimit the areas at the risks for the shootings in free field or closed space.

TURBULENT COMBUSTION

Bray, Ken, Cambridge Univ., UK; Turbulence in Compressible Flows; Jun. 1997, 3.1-3.74; In English; See also 19970021641; Copyright Waived; Avail: CASI; A04, Hardcopy; A03, Microfiche

This review is concerned with turbulent combustion in high speed flows. Its aim is to assess the current state of knowledge incorporated in theoretical models and, as with most turbulent flows, these models necessarily involve averaging. Because high speed turbulent combustion involves additional phenomena which are not well understood, we begin by considering combustion at low Mach numbers where a substantial body of theory exists. Our purpose is to identify the key role played by the low Mach number assumption and hence to define the particular challenge posed by high Mach number reactive flows. Experiments concerning high speed turbulent combustion in jet flames, high speed turbulent deflagration and transition to detonation are reviewed. Finally, problems involved in modeling and prediction of high speed turbulent combustion are identified and discussed. It is concluded that convincing theoretical models are currently not available.

ON THE COMPOSITION OF COMBUSTION GASES OCCURRING AFTER FLIGHT ACCIDENTS AND INCIDENTS AND THEIR ANALYTICAL PROOF OF EXISTENCE

Krause, Harald A. O., Institute of Aviation Medicine, Germany; Sep. 1997; 8p; In English; See also 19970034906; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

In the course of flight accidents and incidents, diverse fires are frequently occurring. As a result, there are mostly gaseous or highly volatile combustion and pyrolysis products are arising which depend on the fire conditions (ventilation, temperature, etc.), the POL (petrol - which is jet fuel, aviation gas, oil, lubricant) in use and the plastic and compound material used in the manufacture of modern aircraft with their characteristic compositions. The exact knowledge of such products and their toxicological qualities is of major importance as well as their definite proof of existence when, according to forensic standards, such occurrences are investigated for possible impairment of human health as a result of flight incidents. The present study provides an overall view of gaseous or highly volatile products possibly resulting from post-crash and in-flight aircraft fires, together with the first results

from a new, high-resolution analytical system for definite substance identification which were obtained at the German Air Force Institute of Aviation Medicine.

Active combustion control is one of the most promising approaches to further optimize the size/weight/power relationship in rockets, ramjets, afterburners, aero-engines, and marine propulsion. A workshop was organized in Athens in spring 1996 under the sponsorship of the AGARD Propulsion and Energetics Panel. It covered the existing knowledge, and further possible strategies for military equipment were discussed within the NATO nations. Further activities are planned.

ROTATIONAL AND VIBRATIONAL TEMPERATURE AND DENSITY MEASUREMENTS BY PLANAR LASER INDUCED NO-FLUORESCENCE SPECTROSCOPY IN A NONEQUILIBRIUM HIGH ENTHALPY FLOW

Koch, U., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Guelhan, A., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Esser, B., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Grisch, F., Office National d'Etudes et de Recherches Aerospatiales, France; Bouchardy, P., Office National d'Etudes et de Recherches Aerospatiales, France; May 1998; 10p; In English; See also 19980203985; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

LIF experiments were performed in the flow field of the high enthalpy facility L2K. This arc heated facility, which is mainly used for testing thermal protection materials, offers a wide choice of flow conditions to simulate the stagnation conditions during shuttle re-entry. The flow conditions are dominated by non equilibrium effects. For the operation conditions of L2K, translational and rotational temperature are assumed to be in equilibrium, but large differences between rotational, vibrational, and electronic temperature occur. Laser induced fluorescence is used to determine rotational and vibrational temperature and the density of NO in the free stream and behind a bow shock upstream of a blunt body. The flow is modelled numerically using a quasi 1D-code. Good agreement is achieved between the experimental and numerical data in the free stream. The data are also compared with the CARS measurements performed at the same flow conditions in the same facility. Differences in the free stream vibrational temperature of N₂ and NO are due to the faster vibrational relaxation of NO-molecules.

This paper describes recent progress in the analysis of the nature of turbulent premixed flames stabilised behind an axisymmetric baffle, which are of fundamental interest in the development of new and cleaner propulsion combustion systems. The work includes the use of laser-based diagnostics for velocity and temperature measurements, which are extended to the analysis of turbulence statistics, including the energy spectrum and typical length scales in a reacting shear layer. The results provided experimental evidence of the extension of the flamelet regime beyond the Klimov-Williams criterion. Arguments based on the shape of the weighted joint probability distributions of axial velocity and temperature fluctuations show that the counter-gradient nature of heat flux is derived from large departures from the local mean values. The influence of swirl in strongly sheared disc-stabilised flames is analysed and the results obtained show that swirl attenuates the rate of turbulent heat transfer due to the decrease of the temperature gradients across the reacting zone, but does not alter the existence of a large zone of flame characterized by non-gradient scalar fluxes.

THE SIMULTANEOUS MEASUREMENTS OF VELOCITY, PRESSURE, TEMPERATURE, AND HEAT RELEASE IN AN OSCILLATING FLAME

Fernandes, E. C., Instituto Superior Tecnico, Portugal; Heitor, M. V., Instituto Superior Tecnico, Portugal; Advanced Non-Intrusive Instrumentation for Propulsion Engines; May 1998; 12p; In English; See also 19980206002; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Optical and probe techniques are used for the analysis of the coupling mechanisms between pressure, velocity, and heat release fluctuations typical of pulsed flames, through the combination of laser velocimetry, digitally-compensated thermocouples, chemiluminescent emissions of free radicals in the flames, and the pressure oscillations upstream flows. The results quantify the periodic nature of the mixing process and characterize the momentum and heat flux fluctuations along a cycle of oscillation.

Fourier Transform Infrared (FTIR) spectroscopy has been used to study the exhaust emissions from a static Rolls Royce Avon gas turbine engine. The thermal infrared emission from the hot exhaust gases was monitored non-intrusively from a distance of 5 meters using a high spectral resolution FTIR spectrometer fitted with a 16 cm aperture telescope. The gas temperatures were determined by comparing the intensity of the measured saturated CO₂ emission band with the radiance of a black body radiation source at known temperatures. CO and CO₂ gas concentrations were determined by comparison with modelled spectra taking into account instrument effects. The results were compared with earlier extractive gas analysis and non-intrusive measurements made on the same engine prior to its recent refurbishment. Improvements in the equipment used for non-intrusive measurements and in the analytical procedures have improved the sensitivity and the confidence with which such quantitative measurements may be made.

Detailed experimental studies of cryogenic propellant combustion are needed to improve design and optimization of high performance liquid rocket engines. A test facility called MASCOTTE has been built up by ONERA to study elementary processes (atomization, droplet vaporization, turbulent combustion...) that are involved in the combustion of liquid oxygen (LOX) and gaseous hydrogen (GH₂). This article reports results from experiments carried-out on MASCOTTE under a consortium of laboratories and manufacturers associating ONERA, CNRS, CNES and SEP, on the jet flame issued from a single coaxial injector. This device fed with liquid oxygen and gaseous hydrogen is placed in a chamber equipped with quartz windows. The spray and the flame are observed with a set of optical methods: high speed cinematography, light emission from OH radicals, laser induced fluorescence of OH and O₂, and elastic scattering from the LOX jet. These techniques are used to obtain images of the spray and of the flame zone. It is then possible to deduce the flame location with respect to the liquid jet from simultaneous elastic scattering of the LOX jet and LIF of OH measurements or from average emission images treated with Abel's transform. The images obtained by exciting the fluorescence of O₂ provide complementary information on the flame shape and they may be used to estimate the local reaction rate. Quantitative temperature measurements based on Coherent Anti-Stokes Raman Scattering from H₂ and LOX droplets size and velocity measurements by means of a Phase Doppler Particle Analyzer give additional clues on the spray and the combustion zone.

The corrosion and stress corrosion cracking behavior of 8090-T81 and 2091-T84 sheet and 8090-T8171 plate aluminum-lithium alloys tested under laboratory and marine exposure conditions are compared with aerospace aluminium alloys currently in service. Initial results are also presented on the corrosion performance of a metal matrix composite aluminium alloy. The corrosion protection of aluminium-lithium alloys is discussed and progress on the development of chromate-free systems and their application to advanced aluminium alloys is described.

EXFOLIATION CORROSION AND STRESS CORROSION CRACKING BEHAVIOUR OF AL-LI ALLOYS

Braun, Reinhold, Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Germany; AGARD, Corrosion Detection and Management of Advanced Airframe Materials; Jan 1, 1995, 12 p; In English; See also 19950017076; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The exfoliation corrosion and stress corrosion cracking (SCC) behavior of damage tolerant sheet and plate materials of aluminum-lithium based alloys in underaged tempers was studied performing different accelerated tests. The EXCO test (ASTM G34) produced blistering and mild exfoliation corrosion. The modified EXCO test suggested by Lee and Lifka proved to be more severe than the standard EXCO test. When exposed to the cyclic acidified salt fog (MAST-MAASIS test according to ASTM G85, Annex A2), the Al-Li alloys studied suffered severe exfoliation. The MASTMAASIS test reproduced marine exposure results for conventional 2024-T351 and 7075-T7351 plates and the limited data for aluminium-lithium based 8090-T81 and 2091-T84 sheets published in the literature. Therefore, it seems to be a promising testing technique to predict the service performance of high strength aluminum alloys. Static loading tests indicated very high SCC resistance for 8090-T8171 and 2091-T8X51 plates in longitudinal and long transverse directions. Environmentally assisted cracking occurred in the latter alloys when stress was applied

in the short transverse direction. Threshold stresses below 100 MPa were obtained from alternate immersion tests (ASTM G44) and from permanent immersion tests in an aqueous solution of 0.5 M NaCl plus 0.1 M LiCl plus 0.05 M NaHCO₃ plus 0.05 M Na₂CO₃. Using the latter synthetic environment, the slow strain rate testing technique indicated sensitivity to stress corrosion cracking for recrystallized 8090-T81 and 2091-T84 sheet materials.

EFFECT OF LOADING DIRECTION AND LONG-TERM AGING ON FATIGUE-CRACK GROWTH IN AL-LI ALLOY 2090**

Anik, M., Middle East Technical Univ., Turkey; Doruk, M., Middle East Technical Univ., Turkey; AGARD, Corrosion Detection and Management of Advanced Airframe Materials; Jan 1, 1995, 9 p; In English; See also 19950017076; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The effect of prolonged exposures up to 1000 Hr at 150, 165 and 180 C on the fatigue-crack were studied in the Al-Li alloy 2090 using the direct current potential drop technique, and results compared with crack growth rates determined in salt water. The CCT specimens, 40 x 200 mm in size, were taken from the sheet material with a thickness of 1.6 mm. Since one of the purposes of this work was to investigate the directionality of fatigue-crack growth behavior, the specimens were machined in the grainflow direction (L-T), long-transverse direction (T-L) and 45 deg to rolling direction (L + 45 deg). The pretreatment applied before the aging consisted of solutionizing at 550 C for one hour followed by 6 percent stretching. According to the air results, the fatigue-crack behavior did not vary significantly with specimen orientations tested in this study. On the other hand, the long-term aging was found to have a pronounced effect on the crack growth kinetics, demonstrated by growth rates which increased up to about 8 fold following aging for 1000 Hr. The rate of the salt-water induced fatigue-crack growth was higher at low values, but lower at high values of Delta K, relative to those obtained in air. Whereas the reduction in roughness induced crack closure effect is believed to be responsible for enhancement at low stress intensity ranges the retardation at high Delta K-values may be attributed to crack-tip electrochemistry, whereby intermetallics with high cathodic efficiency are thought to play a role.

A study was conducted on the corrosion behavior of landing gear steels, AerMet 100, 300M, AF1410, HYTUF and 4340. This study included investigations of stress corrosion cracking and immersion corrosion in an aqueous 3.5 percent NaCl solution, salt spray corrosion in a fog chamber of atomized aqueous 5 percent NaCl solution, humidity corrosion in an atmosphere of vapor from distilled water and hydrogen embrittlement. AF1410 steel is most resistant to stress corrosion cracking, and it is followed by AerMet 100, 0.20C AF1410, HYTUF, 300M and 4340 steels. The immersion corrosion and salt spray corrosion rates of an AerMet 100 steel are 33-40 percent and 13-20 percent those of a 300M steel. In a humidity chamber, AerMet 100 steel is not corrodible in 110 days, whereas 300M steel is quite susceptible to humidity corrosion. Compared to 300M steel, AerMet 100 steel is less susceptible to hydrogen embrittlement.

The surveillance of the actual conditions of materials in aircrafts and the analysis of the influence of flight or standby conditions require detection methods that give quantitative and instantaneous results and that are related to the real degradation process. Electrochemical methods derived from methods used in laboratory have proven to be of interest. The scientific concepts and the instrumentation are generally easily applicable to field conditions; some effort is necessary to develop relevant sensors. The first example applies to the phosphating of carbon steels before painting. The characterization of surface passivation or reactivity can be of interest before and during the surface conversion processes. The second example applies to the detection of crevice corrosion, as may occur in riveted joints.

A study was conducted to identify whether life prediction of high strength aluminum alloys for aircrafts can be determined from short term accelerated atmospheric corrosion tests. The method used is a wet and dry method with electrochemical measurements to characterize the formation or destruction of passive layers. The materials tested include high strength steel 4130, precipitation hardening 15-7 Mo-PH steel and aluminum alloys 6061, 7075 and 2024 with different heat treatments and surface conditions. It appears that the ranking of different Al alloys depends on the type of atmosphere (chloride or acid). The method also clearly showed the detrimental effect of chromated cadmium plating on the hydrogen embrittlement of high strength steel. Corrosion processes of aluminum and high strength steels were clearly identified and useful recommendations could be derived from such tests.

Assembly of carbon fiber composites (CFC) and aluminum structures shall be avoided in unprotected conditions. The more noble CFC could cause fatal galvanic corrosion on the aluminum part. Adequate protection methods for electrical isolation of these dissimilar materials shall be adopted. Adhesion of the coatings on both the CFC and aluminum substrate during exposure to the simulated fuel tank environment is an essential requirement for corrosion protection and fuel tightness of the joint. In a sequence of material and functional tests for selection of adequate coatings and associated materials as well as galvanic corrosion and integral tank aspects have been taken into account. Additional to the static panel test for paint adhesion corrosion tests under dynamic loading and corrosive environment were performed. Based on the experience of these investigations the selected combinations of the coatings, sealants and associated materials were applied on structural tank box for final evaluation. This test article represented the section of a fuselage integral fuel tank structure. For simulation of the complete in-service spectrum, during the life of an aircraft structure, static and dynamic loads were induced. The internal tank environment was simulated by water as fuel replacement and by pressurization of the compartment. Resistance of the CFC/aluminum joint to galvanic corrosion and liquid tightness of the selected integral tank concept proved excellent under simulated conditions.

CORROSION PREVENTION WITH ENVIRONMENTALLY
COMPLIANT MATERIALS: A DESIGN CHALLENGE**

Matz, C. W., Deutsche Airbus G.m.b.H., Germany; AGARD, Corrosion Detection and Management of Advanced Airframe Materials; Jan 1, 1995, 6 p; In English; See also 19950017076; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

In order to eliminate hazardous properties many well proven materials and processes for corrosion prevention have to be replaced. Examples are chromates in primers, sealants and pretreatment processes; and cadmium as plating material and solvents, which usage shall be significantly reduced. The replacement materials often do meet the usual requirements completely. Examples are given how the deficit in performance can be overcome by design changes and supplemental measures.

Corrosion occurs on both military and civilian aircraft as a result of operation in corrosive environments and utilization of less than optimum corrosion preventive measures during fabrication. For low usage rate systems such as military aircraft, corrosion treatment constitutes a high cost maintenance action because corrosion effects can be life limiting mainly due to the fact that current techniques require extensive material loss for reliable detection of corrosion. For high usage systems such as commercial aircraft, corrosion may constitute a safety problem. A recent study by the U.S. Air Force at Tinker Air Force Base has demonstrated that while off-the-shelf nondestructive inspection equipment has some capability for detecting and quantifying aircraft corrosion, significant improvements in both detection and quantification are still required. Results of this study will be briefly reviewed along with discussions relating to some new and innovative inspection technology for detecting corrosion. New concepts and techniques for corrosion monitoring, i.e., detection of onset of corrosion or breakdown of corrosion protection system, will also be discussed.

Advances in electrochemical measurements, thermal imaging, and optical scanning for chemical changes are providing some new research and development opportunities. Finally, concepts relating to damage-revealing chemicals and coatings which may revolutionize the detection and management of corrosion in our systems will be discussed.

To prevent corrosion of military aircraft the design has to be performed with respect to a careful material selection and an effective surface protection treatment of the materials. Protective treatment on aircraft against moisture, humidity, salty atmosphere, industrial environment, hydraulic fluids, fuel, de-icing fluids, combat chemicals etc. is necessary to meet the operation requirements of the aircraft throughout its operational life. Occurring corrosion detected during maintenance shows that not in every case the requirements above can avoid corrosion problems. This report will show some selected examples of in-service corrosion under investigation of the causes. Inspection and repair methods are shown; further recommendations for corrosion prevention and control to reduce corrosion problems based on practical experiences will be given.

The objective of this communication is to present from a comparison of observed corrosions on modern airplanes (Airbus, ATR) and corrosions on older airplanes (Transall, Caravelle) the progress realized in the control of corrosion, based on the adaption of materials and better performing protection. It's necessary today to adapt the techniques and constraints of the new legislative dispositions concerning the environment which bring to research the new materials and protection system.

AXIAL-TORSIONAL, THERMOMECHANICAL FATIGUE BEHAVIOR OF HAYNES 188 SUPERALLOY

Bonacuse, Peter J., Army Research Lab., USA; Kalluri, Sreeramesh, NYMA, Inc., USA; Thermal Mechanical Fatigue of Aircraft Engine Materials; Mar. 1996; 10p; In English; See also 19960021124; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The results of axial-torsional, thermomechanical fatigue experiments on thin walled tubular specimens fabricated from the wrought cobalt-base superalloy Haynes 188 are presented. The fatigue test matrix consists of uniaxial, thermally in-phase (maximum temperature coincides with the maximum mechanical strain) and thermally out-of-phase (maximum temperature coincides with the minimum mechanical strain) experiments; a torsional thermomechanical experiment; a mechanically in-phase (maximum axial mechanical strain occurs at the same point in time as the maximum torsional strain), thermally in-phase experiment; a mechanically in-phase, thermally out-of-phase experiment; a mechanically out-of-phase (maximum axial mechanical strain occurs when the torsional strain passes through zero), thermally in-phase experiment; and a mechanically out-of-phase, thermally out-of-phase experiment. In all the experiments the minimum temperature was 316 C and the maximum temperature was 760 C. The axial mechanical strain range in all experiments but the torsional experiment was 0.8%. The torsional strain range in all experiments with an axial strain component was 1.4%. Four multiaxial life models are used to predict the fatigue lives of these experiments. Using 760 C fatigue life parameters, derived from previous axial and torsional experiments on the same heat of Haynes 188, it was found that the von Mises equivalent strain range and Modified Multiaxiality factor approaches predicted the thermomechanical fatigue lives to within a factor of two of the experimentally observed fatigue lives for all experiments except for the thermally in-phase axial-torsional experiments. Predicted thermomechanical fatigue lives by the Smith-Watson-Topper and the Fatemi-Socie-Kurath parameters were also within a factor of two of the experimental observed fatigue lives, except for the mechanically out-of-phase tests. In general, the largest deviations from the experimentally observed lives were exhibited by the Fatemi-Socie-Kurath model.

SHAPE MEMORY ALLOYS AND THEIR APPLICATION

Boller, Christian, Daimler-Benz Aerospace A.G., Germany; Brand, Werner, Daimler-Benz Aerospace A.G., Germany; Brinson, L. Catherine, Northwestern Univ., USA; Huang, Miin-Shiou, Northwestern Univ., USA; Oct. 1996; 14p; In English; See also 19970001697; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Shape memory alloys (SMA) have gained increasing attraction within the development of aircraft structures. One of the major reasons is, that they allow a recovery of deformation as a result of a transformation process between martensite and austenite, where transformation occurs between characteristic temperature values when being initiated by temperature. So far deformation capabilities of SMA's is mainly taken advantage of by using their two extreme conditions, such as clamped or loose for a fixing element. Continuous control of deformation during this transformation process however allows to take much more advantage of SMA's capabilities but this requires a clear description of the SMA's constitutive behavior which is actually an important area of research. The paper starts by analytically describing the SMA's constitutive behavior using an approach being well understandable for engineering applications. After having explained the basic mechanisms of SMA's it will be shown how these can be analytically implemented into the calculation process for determining the behavior of a simple engineering structure with an integrated SMA-actuator. Finally examples are described, where controlled deformation of a SMA in a smart structure is considered at present.

The effects of different surface modification treatments (shot peening, carbon and nitrogen ion implantation, CuNiIn soft coating, MoS₂ solid lubricant and various combinations thereof) on the fretting fatigue resistance of Ti-6Al-4V and Ti-17 alloys have been investigated. Shot peening produces work hardening and compressive residual stresses in the surface layers, and shows the best improvement in the fretting fatigue life of both Ti-6Al-4V alloy at room temperature and Ti-17 alloy at 278 C. The application of a CuNiIn soft coating plus an overlay of MoS₂ solid lubricant increases the fretting fatigue resistance of baseline Ti-6Al-4V and Ti-17 materials at room temperature and 278 C, respectively, by providing surface lubrication. However, the fretting fatigue life of shot peened plus CuNiIn and MoS₂ coated Ti-6Al-4V material appears to be vendor dependent and, in some cases, the fretting fatigue life is dramatically reduced after the application of a CuNiIn soft coating. This reduction in life may be attributed to the relaxation of compressive residual stresses in the shot peened layers by the plasma spraying process. Both carbon and nitrogen ion implantation improve the fretting fatigue life of baseline Ti-6Al-4V at room temperature. However, the application of carbon or nitrogen ion implantation significantly reduces the fretting fatigue resistance of shot peened specimens.

This paper examines the contributions of fretting and fretting corrosion to the deterioration of one-rivet low lap joints under cyclic loading. Two- and three-dimensional, finite element models of the riveted lap joint are used to define the joint distortion and compliance and to evaluate the mechanical parameters that govern fretting wear and fretting fatigue including the local stresses, cyclic slip amplitudes and corresponding contact pressures at the rivet-panel and panel-panel interfaces. Effects of rivet geometry and plasticity are examined. A piezoelectric fretting wear machine is used to reproduce the relevant contact pressures and slip amplitudes and to measure fretting wear rates for uncoated 2024-T3 and 7075-T6 aluminum sheet in contact with hardened steel and aluminum in relatively dry, laboratory air and 3.5% saline solution. The effects of slip amplitudes in the range 5 to 35 microns on the specific wear rate and coefficient of friction have been evaluated. Predictions based on the results of the modeling and fretting wear and fretting fatigue criteria are compared with experimental observations of cyclically loaded riveted connections.

Historically, many aluminum aircraft components have been made from forgings. However, to reduce airframe manufacturing cost aircraft manufacturers are converting to parts machined from thick plate. The results of recent research indicates that forgings often offer significant advantages over components machined from plate. The purpose of this report is to present this information.

ORGANIC COATING TECHNOLOGY FOR THE PROTECTION OF AIRCRAFT AGAINST CORROSION

Hegedus, Charles R., Air Products and Chemicals, Inc., USA; Spadafora, Stephen J., Air Products and Chemicals, Inc., USA; Eng, Anthony T., Naval Air Warfare Center, USA; AGARD, Corrosion Detection and Management of Advanced Airframe Materials; Jan 1, 1995, 12 p; In English; See also 19950017076; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche; Original contains color illustrations

Coating systems on military and commercial aircraft perform a variety of functions. Clearly, the most critical of these is the protection of aircraft structures from environmental degradation. Protective coatings serve as the primary defense against corrosion of aircraft metallic alloys, as well as degradation of other materials such as polymeric composites. Traditional coatings for aircraft include epoxy primers and polyurethane topcoats. Primers normally contain high concentrations of corrosion inhibitors, such as chromates, and they are designed to provide superior adhesion and corrosion protection. Polyurethane topcoats are formulated to enhance protection and durability; they also provide desired optical effects (i.e., anesthetics or camouflage). More recently, alternative coatings have been developed, such as self-priming topcoats, flexible primers, temporary and multi-functional coatings. These new developments reflect trends in protective coatings technology, changes in aircraft operational requirements/capabilities, and, most dramatically, concerns over environmental protection and worker safety. This issue has created a drive toward coatings with low (possibly zero) concentrations of volatile organic compounds (VOC's) and non-toxic corrosion inhibitors. In turn, these changes have led to concerns over long-term performance, especially protection against corrosion. This paper reviews current organic coatings technology for the protection of aircraft structures and discusses future needs and trends based on advancing technology, environmental concerns, and operational requirements.

Engineering ceramics have enjoyed a growing technological interest in the last decades as high temperature, wear resistant materials. Their low density, low thermal expansion and high hardness associated with a high chemical and mechanical stability in a broad range of temperatures, make them superior candidates as alternative materials for cutting tool inserts, abrasion resistant components, automotive engine parts and aerospace vehicles. The tribological behavior of a Si₃N₄-based ceramic in sliding against tool steel and grey cast iron was investigated. The influence of environmental humidity, sliding speed and temperature on wear of the ceramic is presented and discussed. Laboratory tests were carried out in a pin-on-disc tribometer at variable environmental humidity ranging from 2% to 98%, sliding speed varying from 0.05 ms(exp -1) to 3.5 ms(exp -1), and disc temperatures in the range 22 C to 600 C. The wear mechanisms were investigated using scanning electron microscopy (SEM) with energy dispersive X-ray analysis (EDS). The formation of a tribolayer of wear debris adherent to the contact surface of the ceramic was found to be a determinant in keeping the wear coefficient low. The conditions leading to the formation of such protective layers are identified and discussed.

Advances in solid lubricant technology are required for aerospace systems operating in extreme environments. Targeted operational temperature and lifetime requirements are beyond current capabilities. For example, to increase the thrust to weight ratio in expendable turbine engines, solid lubricants are under development for operation at temperatures to about 800 C. Increases in performance and lifetime for lubricated space based systems are also required. Technological advancements may be achieved through development of new coating materials, processes, and coatings strategies. New materials discussed in this report are oxides and adaptive lubricants. Adaptive lubricants undergo designed chemical reactions with the environment as temperature changes to continually maintain low friction and low wear. Pulsed laser deposition is discussed as an emerging process for growing solid lubricant thin films with complex chemistries and microstructures. Finally, multi-layer coatings that are under evaluation for improving adaptive lubricant performance are discussed.

Increasing demands placed on aerospace systems with respect to performance, lifetime, and operational environment have pushed lubrication and coatings technology to its limit. To meet increased demands, a number of hard, wear resistant coating materials and deposition processes are being developed. Discussion in this paper includes transition metal nitrides/carbides and diamond-like carbon (DLC). In particular, the use of these materials in multilayer and functionally gradient architectures as corrosion resistant, boundary lubricants for candidate high temperature turbine engine oils is highlighted. To effectively use new coating materials, processes that permit the growth of coatings at low temperature are required. This prevents loss

of dimensional tolerance and loss of mechanical properties of precision components. Several low temperature deposition processes are discussed, including a combined pulsed laser deposition - sputter source that permits the growth of infinitely variable gradients and sharp interfaces.

SPUTTER-DEPOSITED LUBRICANT THIN FILMS OPERATING AT ELEVATED TEMPERATURES IN AIR

Zimmermann, C., Dassault Aviation, France; Paulleau, Yves, Commissariat à l'Energie Atomique, France; Tribology for Aerospace Systems; Oct. 1996; 8p; In English; See also 19970006808; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

For the lubrication of sliding contacts operating in hostile environments (vacuum, high temperatures, corrosive ambient, etc.), for which liquid lubricants are ineffective or undesirable, solid lubricant coatings are needed to reduce friction and wear in order to prevent damage. Many solutions such as soft metals (Ag,Pb), lamellar compounds (MoS₂), polymers, and graphite fluoride have been proposed in the last decade. The plasma-sprayed composite PS212 developed by NASA is known as a reference. This thick coating (about 150 microns) is a matrix of metal-bonded chromium carbide (Cr₃C₂) for wear control at high temperatures (800 C) mixed with silver and alkaline earth metal fluorides for the lubrication at respectively low and high temperature. However major drawbacks of these thick coatings are essentially related to its thickness and its roughness; a diamond grinding operation is necessary to adjust the thickness and to improve the surface quality required for a sliding contact. This operation is not easy in small size parts and in ball bearings. The high level of temperature (up to 700 C) required by the spherical bearings of the space shuttle HERMES control surfaces associated with a low friction coefficient (less than 0.3) has needed a specific development. DASSAULT in collaboration with the CENG and ISMCM has developed and tested an innovative thin coating, based on the same compounds as those of the PS212, deposited by a radio frequency sputtering process. A specific test mean, able to conduct tests on spherical bearings under representative conditions of a reentry (temperature, pressure, high load and oscillatory motion) has also been developed.

METALLIC AND NON-METALLIC PROTECTION SYSTEMS FOR REDUCTION OF TRIBOLOGIC INFLUENCES IN SEVERAL AREAS ON TORNADO AIRCRAFT

Hamm, C. D., Daimler-Benz Aerospace A.G., Germany; Blomeier, K., Daimler-Benz Aerospace A.G., Germany; Tribology for Aerospace Systems; Oct. 1996; 12p; In English; See also 19970006808; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The TORNADO multi-role combat aircraft was designed in the 1970's and went into service at the beginning of 1980. From this time up to now several aircraft have achieved approximately 3000 flight hours. With respect to its operational role the TORNADO has been designed as a swept wing aircraft. This type of aircraft with variable wing sweep capability includes in principle more areas which are subjected to sliding and wear than a fixed wing aircraft. Due to this design the affected interfaces of different structural materials have been protected with adequate coatings or materials to maintain the operability of the aircraft. Depending on the function of the movable joints on the aircraft structure, metallic and non-metallic coatings/materials with adequate hardness and wear resistance have been adopted. The range of applied antiwear coatings comprises silver plating against fretting corrosion, abrasion resistant polymers, etc. This paper describes the application of adequate protection methods

in view of their functional integrity in the aircraft structure. Longterm experiences during service life and reparability aspects are discussed.

THE ASSEMBLY OF THERMOPLASTICS BY ADHESIVE BONDING: PROCESS AND CONTROL

Lecomte, J., Centre de Recherches Scientifiques et Techniques de l'Industrie des Fabrications Metalliques, Belgium; Bolted/Bonded Joints in Polymeric Composites; Jan. 1997; 8p; In English; See also 19970019652; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Nowadays, the manufacturing techniques include more and more frequently the assembling of different materials, each dedicated to fulfill one or several requirements of the final assembly. Product designers are therefore induced to consider adhesive bonding of thermoplastic materials, either between themselves or to other materials. Adhesive bonding offers several advantages: weight reduction, better stress distribution in the joint, sealing and insulation. However, this type of assembly, especially when the adherents are thermoplastics, raises many questions about the performances in terms of mechanical resistance, durability, and also about the reliability and the control of the joints. This presentation will consider the four design steps which are of primary importance for the conception of an assembly by adhesive bonding.

PROBABILISTIC EVALUATION OF BOLTED JOINTS IN POLYMER MATRIX COMPOSITES

Chamis, C. C., NASA Lewis Research Center, USA; Minnetyan, L., Clarkson Univ., USA; Jan. 1997; 16p; In English; See also 19970019652; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Computational methods are described to probabilistically simulate fracture in bolted composite structures. Progressive fracture is simulated via an innovative approach independent of stress intensity factors and fracture toughness. The effect on structure damage of design variable uncertainties is quantified. The Fast Probability Integrator is used to assess the scatter in the composite structure response before and after damage. Sensitivity of the response to design variables is evaluated. The methods are demonstrated for bolted joint polymer matrix composite panels under end loads. The effects of fabrication process are included in the simulation of damage in the bolted panel. The results show that the most effective way to reduce the end displacement at fracture is to control the load and ply thickness.

Chromate based pretreatments and chromate pigmented primers are extensively used in the corrosion protection of aerospace aluminum alloys. Current design requirements for UK military aircraft specify the use of either a chromate conversion coating or a chromic acid anodizing treatment on components manufactured from aluminum alloys. This is followed with the application of an epoxy primer containing a strontium chromate inhibitive pigment. Because of concern about the carcinogenic nature of chromates, a research

program to develop non-chromate pretreatments and protective finishes has been undertaken. The results of research into novel inhibitors for aluminum alloys and their application to pretreatments and aircraft primers are presented. Several promising inhibitors including cerium salts, sulphur containing compounds and oxoanions have been identified. Whilst none of the systems so far investigated give the same level of protection as chromate based treatments, progress towards a chromate-free protection scheme is being made.

Current metal surface preparation processes typically rely on materials that are undesirable from environmental or safety perspectives, such as strong acids/bases and hexavalent chromium. In addition, these processes usually produce large wastewater streams. The USA Air Force (USAF) Wright Laboratory is investigating alternate surface preparation approaches in order to develop and transition processes that are environmentally friendly with equal or improved performance. Several technologies are being evaluated, primarily for adhesive bonding of aluminum and titanium. These include: excimer laser, plasma polymerization, ion beam enhanced deposition, plasma spray and sol-gel. These approaches eliminate or greatly reduce the undesirable environmental impact of the currently-approved processes. Most of the candidates deliver bond strength performance equivalent to these existing procedures. As measured by accelerated laboratory testing, none consistently provide the long-term moisture durability of the state-of-the-art. However, some candidates outperform existing, accepted processes and appear to be capable of delivering state-of-the-art moisture durability once optimized. At this time, sol-gel provides the best combination of performance and ease of scale-up for depot and field applications. With this approach, a water-based solution is applied to the metal and dried at elevated temperature without rinsing. Environmentally friendly pretreatment (cleaning and deoxidizing) and post-treatment (priming) steps are used. Future work will continue optimization and scale-up efforts for solgel and other viable candidates. Transition to USAF and other users will be pursued. High-temperature titanium bonding and on-aircraft aluminum bonding are potential early transition opportunities.

QUALIFICATION OF CHROMATE-FREE PRIMERS FOR APPLICATION TO AIRCRAFT STRUCTURE

Higgins, A., AVRO International Aerospace, UK; Feb. 1997; 10p; In English; See also 19970023078; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

Paint primers used on metallic aircraft structure are the major contributing element in the protection of the structure against corrosion. Qualification testing of primers for use on aircraft structure is therefore aimed at assessing if adequate service performance can be achieved. All assessors use accelerated degradation testing based on long term immersion in fluids to which the aircraft structure will be subjected in service, thermal cycling, exposure to high humidity and various corrosion tests. Accelerated corrosion testing is the primary method used in most qualification specifications for assessing service life expectancy of the primed metallic surface. The variability of service conditions and the lack of precise data of service life to corrosion test performance make this assessment subjective. The general performance of chromated primers in service can be used to compare respective accelerated corrosion test performance of alternative primers. Consideration needs to be given to the fact that chromated primers are capable of protecting structure for well past the airframe service life in most areas. This means that chromate-free alternatives with lower accelerated test performance could be considered for areas of the structure where the performance in service is assessed to be adequate. The variation in approach to assessment and in the test methods used by different airframe manufacturers and those called up

in national specifications needs to be rationalized and better defined if the primer manufacturers are to be able to provide the airframe industry with a suitable chromate-free alternative primer.

Thermal barrier coatings are an emerging technology which will allow either increasing the inlet turbine temperatures or on the other hand decreasing the working temperature of the metal of the blades and consequently increasing their life-time. The Workshop allowed a survey of the state of the art, a description of the existing technologies or of the technologies under development, a review of the present knowledge of damage mechanisms, including microstructural, mechanical and thermal aspects, and an account of the advantages and drawbacks of the various families as perceived by engine manufacturers and users. A final discussion was held to identify the needs for further R & D.

In this paper, the importance of the challenge associated with the control of the thermal conductivity of thermal barrier coatings for turbine engines hot stages is being reviewed (yttria stabilised zirconia mostly). It is firstly illustrated by the description of a practical aeronautic coated and uncoated turbine blade design exercise. The various contributions to TBC thermal conductivity are then reviewed. Their low conductivity finds its source not only in the nature of the ceramic layer (highly disordered material), but also in the morphology of the insulating layer, closely linked to its fabrication process parameters. The influence of various factors (such as yttria content, temperature, porosity content and distribution, etc.) on the thermal conductivity is examined, largely based on a literature review. In this field of investigation, the modelling tool should allow to predict, to a certain extent, which morphology would lead to the lowest values of thermal conductivity. Eventually attempts are made to identify research domains where further understanding is needed, and to formulate several suggestions concerning possible ways to lower the thermal conductivity.

This paper presents a review of our present knowledge in the formation of plasma sprayed Thermal Barrier Coatings (TBCs). The

following points are examined for TBCs made of zirconia partially stabilized with 8 wt % of yttria: (1) Characteristic times for particle flattening, splat cooling, and solidification with the corresponding cooling rates and microstructure. (2) Critical preheating temperature of substrates or previously deposited layers to achieve a good contact with splats. An explanation of the effect of this critical temperature is proposed. (3) Times between two impact events at the same location and two successive passes. The consequences on the mean temperature within coating in conjunction are underlined for various substrate and coating cooling devices. (3) The effect of substrate critical temperature and substrate oxidation stage on coating adhesion/cohesion. (4) Splat layering and temperature conditions at which a columnar structure can grow through the whole coating. The consequences on stresses development during and after spraying and coating Young's modulus, are discussed. (5) At last, the parameters which have to be controlled during spraying to achieve a much better reproducibility of coatings. A special emphasize is given to torch voltage fluctuations related to electrodes erosion, powder injection conditions and finally substrate and coating temperature before (preheating) during and after (cooling) spraying.

Plasma-sprayed TBCs are built by the successive addition of molten or partially-molten particles spreading upon impact on the substrate surface. Consequently, the temperature and velocity of the sprayed particles are among the most important parameters influencing the microstructure and properties of the deposited coatings. On-line measurement of these parameters, as well as the particle trajectories, is thus an efficient way to monitor the state of the spray process. This approach should permit to minimize the influence of uncontrolled parameters such as the electrode wear or changes in particle injection conditions. A rugged and easy-to-use optical sensor system has been developed to perform on-line particle diagnosis during spraying in a production environment. In this system, the thermal radiation emitted by the in-flight particles is collected by a compact sensing head and transmitted through an optical fiber bundle to a detection cabinet located away from the dusty environment around the plasma torch. In this paper, a review of some applications of this diagnosis system used to determine the influence of the spray parameters on the particle temperature, velocity and trajectory and to control the spray process during deposition of TBCs are presented. The system was used in production at Pratt & Whitney Canada (PWC) for two months giving information about the stability and reproducibility of the plasma spray process.

Basic features for future advanced gas turbines will be low emission rates and increased efficiency. To fulfil these requirements a

reduction of cooling air in the combustor chamber demanding more efficient cooling technology and/or an development inner wall temperature is needed. The development of thicker thermal barrier coatings for combustor tile applications is one concept followed to enable a reduction in cooling air. Thermal barrier coatings with a thickness up to 2mm and improved thermal cycling life have been developed as well as mechanical and thermophysical data determined. Combustor segment rig testing demonstrated a potential of 25% cooling air reduction by the use of thick thermal barrier for the tile design investigated.

ADVANCED PROCESSING OF TBC'S FOR REDUCED THERMAL CONDUCTIVITY

Nicholls, J. R., Cranfield Univ., UK; Lawson, K. J., Cranfield Univ., UK; Rickerby, D. S., Rolls-Royce Ltd., UK; Morrell, P., Rolls-Royce Ltd., UK; Apr. 1998; 10p; In English; See also 19980197432; Copyright Waived; Avail: CASI; A02, Hardcopy; A10, Microfiche

Zirconia-8wt% yttria thermal barrier coatings (TBC's) provide the potential to increase the operating temperatures within the modern aeroengine gas turbine. of particular interest are the columnar, strain tolerant thermal barriers produced by electron beam physical vapour deposition which can be applied to rotating components and can reduce the metal surface temperature by up to 150 C. Measured thermal conductivities for this columnar microstructure are typically 1.8-2.0 W/m.K. Should it be possible to reduce this value to that observed for plasma sprayed ceramics (0.9-1.0 W/m.K) then further benefits from the use of such a ceramic layer could ensue including either a further increase in operating temperature or a reduction in cooling air requirements. This paper examines the advanced processing of TBC's with the aim of reducing thermal conductivity. The role of coating thickness is reviewed, where it is shown that for thin coatings, circa 100 micro-m thermal conductivities of 1.0 W/m.K can be achieved. This is thought to be due to increased scattering of thermal waves close to the early confused growth region. The possibility of further reducing thermal conductivity by using layered structures is examined. These structures have been manufactured by control of rotation, controlled dwell and through the use of plasma assistance during the deposition process. The benefits of such layers in scattering thermal waves is discussed.

TBCS ON FREE-STANDING MULTILAYER COMPONENTS

Tsantrizos, P. G., PyroGenesis, Inc., Canada; Kim, G. E., PyroGenesis, Inc., Canada; Brzezinski, T. A., PyroGenesis, Inc., Canada; Apr. 1998; 8p; In English; See also 19980197432; Copyright Waived; Avail: CASI; A02, Hardcopy; A10, Microfiche

PyroGenesis Inc. has developed a unique process for the production of components designed to operate in the hot section of gas turbines. The new process involves spray forming multilayer components by Vacuum Plasma Spraying (VPS) onto molds and subsequently separating the mold from the near net-shape free-standing component. Advanced TBCs have been developed and incorporated into the multilayer structure in an effort to extend the component's high temperature performance capabilities. The spray formed components are heat treated to improve the mechanical properties of the superalloys. PyroGenesis has used the VPS near net-shape forming process to fabricate closed components with a TBC inner layer, consisting of calcia silica (Ca₂SiO₄) and zirconia partially stabilized with yttria (PSZ), a CoNiCrAlY bond coat, and an IN-738LC outer layer. Preliminary results indicate that the spray formed components have excellent mechanical properties, can operate at much higher temperatures than similar conventionally fabricated components and require less cooling. The TBCs showed uniform thickness and microstructure with a smooth surface finish. The bond coat and structural superalloy layers were very dense with no signs of oxidation at the interface. After heat

27 NONMETALLIC MATERIALS

treatment, the mechanical properties of the IN-738LC compare favourably to cast materials. Finally, the cost of spray forming multilayer components is lower than the cost of conventional fabricating options.

The need for improving the performance and maintenance costs of gas turbine engines has led to the development of advanced thermal protection systems for critical components such as high pressure turbine (HPT) blades and vanes. This led to the concomitant development of advanced coating deposition techniques. Electron beam physical vapour deposition (EB-PVD) first made possible the application of corrosion resistant overlay coatings on turbine blades. The EB-PVD technology has since been gaining ever more interest world-wide as it stands as the best industrial technique for the deposition of thermal barrier coatings on first stage HPT aerofoils. The strategic nature of the EB-PVD process means that it has been developing somewhat independently on both sides of the iron curtain during the cold war years. Today, both American and ex-USSR technologies are open to the market. This is the object of this paper to compare the two state-of-the-art both from a deposition process standpoint and from a laboratory evaluation on samples. This evaluation covers structural studies as well as thermal cycling testing. The relationship between the deposition process and the coating functional behaviour is discussed.

Thermal barrier coatings (TBCs) are increasingly applied to hot components in gas turbines. Contrary to plasma spraying, the electron-beam physical vapour deposition (EB-PVD) process offers the opportunity to generate coatings having a unique columnar microstructure. The main advantage of this structure is its superior tolerance against straining and thermoshock, thus giving it a major edge in lifetime. Furthermore, cooling hole closure will be prevented and the aerodynamic design of the blades will be maintained. This paper will outline the advantages of EB-PVD for the production of TBCs on rotating gas turbine components like blades and vanes. The effect of EB-PVD processing parameters on the microstructural evolution and respective lifetimes of partially yttria stabilised zirconia (PYSZ) TBCs will highlight the potential of the evaporation process. Alternative stabilisers like Ce and La are looked at in terms of increase of application temperatures as well as life extension of the blades. An extended structural zone diagram for PVDs proposed incorporating the influence of substrate rotation on microstructural evolution. Finally, the limits of evaporation processing will be stressed.

Plasma-assisted chemical vapor deposition has been successfully used to deposit thick (20 - 150 micron) zirconia - (5-20wt%) yttria coatings on metallic and alumina substrates, with high rates (up to 150 micro-m/h) at temperatures ranging from 400 to 750 C. Tetrachloride (ZrCl₄) and Y(thd)₃ beta-diketonate were used as zirconium and yttrium source materials. Vaporization conditions have been studied for both precursors. Morphology, impurity content, and crystallographic structure of the coatings were investigated. At all deposition temperatures, the coatings exhibited columnar morphology and {100} crystallographic texture. At low substrate temperature (400 C), the pore volume fraction was high (ca. 50%) and the coatings incorporated some carbon and chlorine impurities, but at high temperature (750 C), the pore fraction reduced to about 25% and little carbon and no chlorine were detected. Metastable tetragonal <t> phase was the main constituent of coatings with 7 and 10wt% yttria. Annealing for 24 and 120 hours of ZrO₂ - 7wt% Y₂O₃ coating deposited at 400 C showed that cubic phase with an yttria content of about 1wt% is allowed to form, at the expense of the <t> phase whose yttria content diminishes to 4wt%. This relatively fast evolution towards thermodynamic equilibrium may be related to the high porosity level.

Nanostructured ceramics exhibit a number of enhanced mechanical and thermal properties which may make them attractive as thermal barrier coatings. The phonon contribution to thermal conductivity is greatly reduced at room temperature, but becomes significant at operating temperatures only for grain sizes below 20 nm. Improvements in mechanical properties such as fracture toughness and resistance to spalling, can be achieved at larger grain size. In the range of 30 - 70 nm. Suitable coatings, consisting of a composite of zirconia with a second immiscible phase, such as alumina, can be fabricated by thermal spray. However, development of techniques to produce the required microstructure are at an early stage and may require advances in the state of the art for thermal spray technology.

The thermal conductivity of ceramic coatings is a function of the thermal conductivity of the individual constituents (nature of phases, presence of point and planar defects, etc.) and of the morphology of the coating (pores, cracks). This latter aspect is particularly important for TBCs as it explains why their thermal conductivity is significantly

lower than the corresponding values for dense materials. This paper presents a model developed to calculate the thermal conductivity of porous and microcracked ceramic coatings based on a finite difference method applied on digitized images of yttria partially stabilized zirconia (YPSZ) coatings deposited by plasma spraying. The influence of the different types of morphological features on the thermal conductivity is discussed.

Thermal conductivity is an important design parameter for thermal barrier coatings. Accurate thermal conductivity data is therefore required to ensure proper design and reliability of gas turbine blades. In the present research, thermal conductivities of Al₂O₃ and 8wt.% Y₂O₃ stabilized ZrO₂ (8YSZ) coatings, including monolithic and multilayer configurations, made by air plasma spray (PS) and electron beam physical vapor deposition (EB-PVD) techniques, were determined from the measurements of thermal diffusivity and specific heat as a function of temperature. Thermal diffusivity was determined by the laser flash technique. Specific heat was determined by a Differential Scanning Calorimeter (DSC). Detailed analyses of the results indicate that in the case of PS coatings, the thermal conductivity is sensitive to coating density (porosity), interfaces between splats as well as the interface between the coating and the substrate. In the case of EB-PVD coatings, it is shown that the multilayer conductivity is simply a series representation of monolithic coatings, provided comparisons are made under same microstructural condition. Further, analyses of sensitivity of the laser flash technique to variations in the coating and the substrate parameters, for the coatings evaluated in this study, were also performed. The results are discussed in the context of coating characteristics, reference conductivity data for dense materials and the sensitivity of the measurement method to coating parameters.

A series of thermal barrier coatings were deposited on superalloy pins by various techniques using different processing parameters, in order to optimize the durability of the coatings for aerospace applications. These coatings were subjected to simulated high temperature engine operating conditions in a high velocity burner rig. The durability of the coatings at different temperatures was assessed at regular intervals from changes in pin weight due to oxidation and/or loss of coating. The thermal characteristics of some of the coatings were also assessed on-line by monitoring the core temperatures of the pins. After thermal cycling, the specimens were subjected to metallographic

examination, to study the change in microstructure brought about by the burner rig cyclic tests. The test methodology and the results are discussed.

GRADED DESIGN OF EB-PVD THERMAL BARRIER COATING SYSTEMS

Schulz, U., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Krell, T., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Leushake, U., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Peters, M., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Apr. 1998; 10p; In English; See also 19980197432; Copyright Waived; Avail: CASI; A02, Hardcopy; A10, Microfiche

The most durable TBCs (Thermal Barrier Coatings) are yttria partially stabilized zirconia coatings which are applied by EB-PVD (Electron Beam Physical Vapor Deposition) on metallic bond coats. The EB-PVD process offers the advantage of a superior strain and thermoshock tolerant behavior of the coatings due to their columnar microstructure. The interface between ceramic and metal is the weakest link in this system. Spallation occurs in that area which is mainly attributed to oxidation of the bondcoat and to thermomechanical stresses of this two-layered coating. The concept of graded materials is one approach to lower both stresses and also oxidation of the bondcoat. This concept is presented in detail with special emphasis on chemically graded alumina-zirconia TBCs. Microstructures and phases of alumina, alumina-zirconia, and of graded coatings deposited by EB-PVD are evaluated. Mainly alumina undergoes phase transformation in the mixed and graded layers from the amorphous state to the desired alpha-Al₂O₃. Finite element modeling was performed to study the influence of coating thickness and composition on heat flux and stress distribution.

Bond coat oxidation has been clearly established as a factor contributing to the failure of a TBC. However, the mechanism by which oxidation effects TBC failure has not been determined. Similarly, other bond coat properties have been cited as influencing TBC residual stresses, but neither the magnitude of the effects nor the exact mechanisms by which these properties act, and interact, have been elucidated. A finite element model was developed to evaluate residual stresses induced by thermal cycling of a typical plasma sprayed TBC system. It was found that bond coat properties of oxidation, creep, coefficient of thermal expansion (CTE) and roughness, as well as top coat creep, all strongly influence ceramic layer stresses. Roughness and CTE were found to have the strong effects in a parametric study, acting primarily as stress multipliers for other active mechanisms. A detailed examination of the time dependent properties of creep and oxidation indicates that these factors account for evolution of the

28 PROPELLANTS AND FUELS

residual stresses with thermal cycling. It is the combination of these effects over the lifetime of the coating that drives the generation of stresses required to initiate and propagate delamination cracks.

THE EFFECT OF TBC UTILIZATION IN THE DESIGN OF ROBUST AIRCRAFT COMBUSTORS

Arana, Carlos A., Wright Lab., USA; Apr. 1998; 10p; In English; See also 19980197432; Copyright Waived; Avail: CASI; A02, Hardcopy; A10, Microfiche

As performance objectives of new and derivative military engines require combustion systems to operate at higher pressures and temperatures, balancing conflicting demands of improved durability, stability, and operability becomes more difficult without technology improvements in combustor liner designs. Since combustor thermo-mechanical fatigue is currently a significant contributor to engine life cycle costs, improved structural durability must be achieved, without compromise of other combustor requirements. This paper addresses the application and verification of liner cooling schemes and their interaction with thermal barrier coatings (TBCs) for the design of robust aircraft turbine engine combustor liners to meet the above mentioned demands. An analytical investigation was conducted to determine the effect of TBCs on the average metal temperature for a full annular, semi-transpiration cooled combustor liner. The perspective is from a customer's viewpoint, a combustor liner designer who is continuously challenged to increase combustor temperature rise capability and operability for new products while maintaining cooling flow levels.

19980197449 Rolls-Royce Ltd., Derby, United Kingdom ADVANTAGES/DISADVANTAGES OF VARIOUS TBC SYSTEMS AS PERCEIVED BY THE ENGINE MANUFACTURER

Morrell, P., Rolls-Royce Ltd., UK; Rickerby, D. S., Rolls-Royce Ltd., UK; Apr. 1998; 10p; In English; See also 19980197432; Copyright Waived; Avail: CASI; A02, Hardcopy; A10, Microfiche

This paper discusses the relative advantages and disadvantages of Thermal Barrier Coatings systems (TBC's) produced by thermal spraying and electron beam PVD processing technology from a design point of view. This paper reviews the structure/property relationships for electron-beam physical vapour deposition (EB-PVD) TBC's in contrast to those of plasma sprayed TBC's, particularly with respect to thermal conductivity, erosion resistance, and mechanical behaviour. Examples are used to show how, through the development of customized bond coat systems, the performance of TBC systems can be considerably enhanced, an important incremental step towards the ultimate goal of "designed-in TBC's".

Luminescent molecular probes imbedded in a polymer binder form a temperature or pressure paint. On excitation by light of the proper wavelength, the luminescence, which is quenched either thermally or by oxygen, is detected by a camera or photodetector. From the detected luminescent intensity, temperature and pressure can be determined. The basic photophysics, calibration, accuracy and time

response of a luminescent paint is described followed by applications in low speed, transonic, supersonic and cryogenic wind tunnels and in rotating machinery.

EFFECTIVE SPECTRAL EMISSIVITY MEASUREMENTS OF SUPERALLOYS AND YSZ THERMAL BARRIER COATING AT HIGH TEMPERATURE USING A 1.6 MICRON SINGLE WAVELENGTH PYROMETER

Alaruri, Sami, Allison Engine Co., USA; Bianchini, Lisa, Allison Engine Co., USA; Brewington, Andrew, Allison Engine Co., USA; May 1998; 12p; In English; See also 19980206002; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A method employing an integrating sphere and a single wavelength (1.6 micron) pyrometer for measuring the spectral effective emissivities of superalloys in the temperature range (approx. 650-1050 C) is described. The spectral effective emissivities for five superalloys, namely, MARM-247, MARM-509, CMSX-4, Inconel-718, N-155, and two Rene-N6 samples coated with YSZ thermal barrier coating were measured. Correcting the pyrometer measurements for the variations in the object emissivity would reduce the uncertainty in the temperature measurements to less than +/- 1%.

The Conference Proceedings contains papers presented at the Propulsion and Energetics Panel 84th Symposium on Environmental Aspects of Rocket and Gun Propulsion which was held on 29 Aug. - 2 Sept 1994, in Aalesund, Norway. The Technical Evaluation Report and the Keynote Address are included at the beginning and discussions follow most papers. The Symposium was arranged in the following sessions: Clean Propellants (7); Propellant Development (6); Measurements (7); Disposal (3); Material Recovery and Re-Use (8); Contamination (5).

SOLID PROPELLANTS FOR SPACE LAUNCH VEHICLES NOT GENERATING OR LITTLE HYDROCHLORIC GAS PROPERGOLS SOLIDES POUR LANCEURS SPATIAUX GENERANT PAS OU PEU DE GAZ CHLORHYDRIQUE

Perut, C., Centre de Recherches du Bouchet, France; Bodart, V., Centre de Recherches du Bouchet, France; Cristofoli, B., Centre de Recherches du Bouchet, France; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 12 p; In French; See also 19960008937; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Solid propellants for space launch vehicles do not generate, or generate just a little of hydrochloric gas. The conventional propellants for accelerators of space launch vehicles contain as an oxidant ammonium perchlorate and generate, as a result, hydrochloric gas. Although

the effects on the environment are extremely weak, the studies are conducted to reduce this impact even further. The SNPE engaged the work along two axes, the propellants containing ammonium with high perchlorate rates and a chlorine sensor, and the formulations not containing a chlorinated species. This article describes the results obtained on the first type of composition. The propellants with chlorine sensor present a voluminal specific impulse of a level identical to that of the current compositions, but a weaker specific impulse, and good rheological, mechanical and ballistic properties. Experiments carried out on the effluents of engine of 1 kg or 40 kg made it possible to validate the concept and the choice of the formulations. The hydrochloric rate of acid, measured by an electrochemical method and infra-red spectrometry, is very strongly reduced, by approximately a factor 100. The rates of oxide of nitrogen, determined by chemiluminescence remain weak. The morphology and the grain size collected are given.

CLEAN PROPELLANTS FOR SPACE LAUNCH BOOSTERS

Beckman, Charles, Phillips Lab., USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 9 p; In French; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The Phillips Laboratory Propulsion Directorate has been developing propulsion systems for space launch application which address environmental concerns (the clean propellant programs) since the late 1970's. The Applications Division (RKA) developed an environmental approach to eliminate hydrochloric acid as an exhaust product. This approach is in line with the Air Force space launch propulsion strategy. Application of environmentally acceptable propellant technology is evident in each step in the manufacturing process through conservation/disposal. Future propulsion systems will be required to comply with environmental regulations and laws. The Environmental Protection Agency has raised concern about acid rain and is calling for significant reduction of hydrochloric acid in the atmosphere. They have developed models to predict the environmental impact of hydrochloric acid from space launches in the atmosphere and its role in ozone depletion. The space launch strategy team stressed that these predictions of environmental impact need to be substantiated with hard data. It is essential that the space launch propulsion community develop alternative environmentally acceptable space launch propulsion systems. Development of space launch scavenger propellants has significantly reduced the amount of hydrochloric acid released into the atmosphere from greater than 20 percent to less than 2 percent. Solution propellant technology has potential as a chlorine-free propellant for space launch application. Advanced Environmental Propellant Development will evaluate high energy ingredients to replace current low density or low performance ingredients in propellant formulations to achieve equal or better performance than current solid systems. These steps are essential to ensure the future of space launches.

Due to environmental aspects of solid propulsion, the possibility to reduce or eliminate the concentration of HCl in rocket exhausts without compromising performance is of interest. This can be achieved in different ways. In an AP based propellant AP may be partially or fully replaced by another oxidizer. The influence on the amount of HCl in a rocket exhaust by partial replacement of AP with HMX in a specified AP/HTPB based propellant is presented together with effects on

various other propellant properties. This include computer simulations and experiments on the energy content and the rocket exhaust signature as well as tests on mechanical and hazard properties of the propellant.

Propellants based on ammonium nitrate and GAP are candidates not only for less polluting but high energetic, minimum smoke propellants with reduced sensitivity. They may act as suitable candidates for the substitution of double base propellants so far used in rocket motors for tactical defense. The difficulties for the development of such a propellant system depend on the chemical nature and problems connected to the ingredients. Drawbacks are caused by the numerous phase changes of AN, its hygroscopicity, lower energy and low reactivity. The key problems for the development are the unfavorable combustion behavior and sometimes bad stability of AN/GAP formulations. Some of the main features of these propellants have been developed and illustrated in this paper. These are performance, chemical stability combustion behavior and detonation sensitivity. Four different kinds of pure and phase stabilized ammonium nitrate are compared regarding stability and combustion behavior in propellant formulations with GAP and nitrate ester plasticizers. In consideration of stability, performance and detonation sensitivity the system of pure AN (SCAN), GAP, TMETN, BTTN without nitramines has been chosen for further development.

DEVELOPMENT OF ENVIRONMENTALLY ACCEPTABLE PROPELLANTS

Chan, May L., Naval Air Warfare Center, USA; Demay, Susan C., Naval Air Warfare Center, USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 5 p; In English; See also 19960008937; Copyright; Avail: CASI; A01, Hardcopy; A03, Microfiche

The propellant formulations at the Naval Air Warfare Center Weapons Division, China Lake, CA, following the guidelines of Insensitive Munitions and the global emphasis on a clean environment, have been developing environmentally responsible and insensitive propellant formulations for future weapon use. In this paper, a family of minimum-signature propellants composed of GAP and AN will be described. These propellants have shown excellent processing, mechanical, and combustion properties. In addition, they are considerably less sensitive to shock, heat, and mechanical impact than the conventional propellant material. This paper also summarizes the results of studies conducted on ADN to establish its properties when used in propellant applications. The research work primarily involved determining the safety characteristics of neat ADN and ADN propellant compositions, evaluating the thermocompatibility of ADN with a number of energetic binder ingredients, and examining the processing and aging properties of potential energetic binder/ADN propellants.

Hydrazinium nitroformate (HNF) is viewed as a promising new oxidizer. It has a high energy content and does not contain chlorine. When combined with an energetic binder like glycidyl azide polymer (GAP), high performance tactical propellants with low signatures are obtained. When adding aluminum fuel to the formulation, improved propellant performance is obtained for propellants suitable for space applications. In this paper, environmental, plume signature and theoretical performance aspects of HNF/GAP based solid propellants are considered, and the ballistic and material properties of HNF are summarized.

SHOCK SENSITIVITY OF AMMONIUM NITRATE BASED PROPELLANTS

Campos, J., Coimbra Univ., Portugal; Gois, J. C., Coimbra Univ., Portugal; Mendes, R., Coimbra Univ., Portugal; Cortez, P., Instituto Nacional de Engenharia e Tecnologia, Portugal; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 7 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Ammonium nitrate (AN) is the base component of a recent family of gas generators and rocket composite propellants with lower pollutants. They have the same polyurethane (PU) binder based in hydroxyl terminated polybutadiene (HTPB), a plasticizer (DOA) and a curing agent (IPDI), of the classic ammonium perchlorate (AP) based composite propellants. The impossibility of burn a pure AN-PU propellant at atmospheric pressure, with AN concentration standard of 80 weight percent, leads to find an inert additive component in order to increase insulation and decrease global initial density. The glass microballoons (GMB) have these properties. AN-PU-GMB composites varying the AN concentration from 80 to 90 percent, keeping constant the 4 percent of GMB, are our tested compositions. The existence of detonation regime in a propellant shows the security level at non-stationary regimes and at fragment impact initiation. An experimental technique to measure initiation of propellant, with a shock induced from a plastic explosive, is presented. A double resistive wire was placed coaxially inside acceptor, in order to allow the continuous measurement of detonation velocity and the position of extinction section, when it occurs. An aluminum crush bar, under detonation plate, shows clearly the extinction section zone. Experimental results show any initiation of detonation of mixtures AN-PU-GMB with concentration of AN lower than 83 percent. It is observed the initiation of AN-PU-GMB propellant with concentrations of AN of 83 percent, followed by extinction, near 110 mm, also verified by the observation of shocked propellant sample and crushed bar profiles. It was measured the initiation of AN-PU-GMB of concentrations of AN of 90 percent, followed by a non-stable detonation, with a detonation velocity of approx. 3200 m/s, and a periodicity of interruptions of period distance of approx. 5 mm. The obtained results prove the validity of tested procedures and show the possibility of using 4 percent of GMB as additives, in AN-PU base propellants with concentration of AN up to 83 percent.

POSSIBLE WAYS OF DEVELOPMENT OF ECOLOGICALLY SAFE SOLID ROCKET PROPELLANTS

Manelis, G. B., Academy of Sciences (Russia), Russia; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 7 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The combustion products of conventional solid rocket propellants are known to comprise substantial quantities of pollutants, primarily hydrogen chlorides and other chlorine-containing compounds, carbon monoxide, and fine particulate alumina. Some propellants yield additionally to above-mentioned, highly toxic beryllium and fluorine compound. The concentration of the pollutants at the nozzle outlet can be essentially evaluated by thermodynamic calculation on the basis of the chemical composition of the propellant and conditions of stationary work of the engine. The evolution of the pollutants in the environment after they leave the nozzle is investigated but poorly. One can assume, however, that formation of the products of incomplete oxidation - dioxines and other carcinogenes, in particular - is highly likely, especially on the stages of ignition and extinguishing of the engine. The main source of the pollutants in the combustion products is the ammonium perchlorate (NH₄ClO₄), which is main oxidizer in conventional solid propellants.

Current composite propellant compositions for rocket motors make use of ammonium perchlorate (AP) and aluminium in a polyurethane binder based on a hydroxy terminated polybutadiene (HTPB). Increasing concern for the environment has resulted in a great deal of effort being devoted to finding replacements for AP which has a tendency to produce large amounts of HCl during combustion. Ammonium nitrate (AN) has been considered in the past as a replacement for AP but its use has been limited due both to a reduction in ballistic performance associated with its use, and to problems connected with phase changes in AN which can occur during the storage of AN or AN based propellants. Recent developments in the field of energetic binders have however resulted in the availability of several polymers such as polyNIMMO (PN), polyGLYN (PG), and glycidyl azide polymer (GAP), which when used in conjunction with AN, compensate for any reduction in performance caused by the replacement of AP. Similarly the use of phase stabilized grades of AN have minimized the problems associated with phase changes in AN on storage. The present paper details the work that was carried out at ICI Explosives in Scotland and the Defence Research Agency at Fort Halstead in England which led to the development of an insensitive low visible signature propellant formulation based on the use of ammonium nitrate with plasticized polyNIMMO as the binder. Theoretical calculations on a range of candidate compositions along with the ballistic, sensitiveness and rheological properties of the propellant formulation are described. In addition various options for its further development are considered.

USE OF NEW OXIDIZERS AND BINDERS TO MEET CLEAN AIR REQUIREMENTS

Demay, S., Naval Air Warfare Center, USA; Braun, J. D., Naval Air Warfare Center, USA; AGARD, Environmental Aspects of Rocket and

Gun Propulsion; Feb 1, 1995, 4 p; In English; See also 19960008937; Copyright; Avail: CASI; A01, Hardcopy; A03, Microfiche

The burning of conventional solid rocket propellants introduces various substances into the atmosphere, including such noxious materials as hydrochloric acid and other reactive chlorine compounds, uncombusted fuel species, and toxic heavy metal oxides, as well as lighter metal oxides and alkali metal oxides. These materials can contaminate the natural landscape and water sources, degrade atmospheric quality, and even have the potential to affect atmospheric behavior (e.g., through ozone depletion). Advanced new energetic oxidizers and binders now being investigated, used in conjunction with selected conventional propellant ingredients, will allow the formulation of new propellants that will eliminate nearly all of these contaminants and still possess a high measure of performance. Oxidizers include an inorganic derivative of nitramide acid and a dense 3-dimensional cyclic nitramine having high oxygen balances and favorable heats of formation. Binders include polyglycidyl and polyoxetane derivatives containing energetic azido or nitrate structures.

EVALUATION OF AMMONIUM NITRATE PROPELLANT EMISSIONS

Stowe, R. A., Defence Research Establishment Valcartier, Canada; Lessard, P., Defence Research Establishment Valcartier, Canada; Roy, G., Defence Research Establishment Valcartier, Canada; Richer, G., Defence Research Establishment Valcartier, Canada; Benchabane, M., Bristol Aerospace Ltd., Canada; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 12 p; In English; See also 19960008937; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Defence Research Establishment Valcartier has recently completed the exploratory development of a solid rocket propellant based on an ammonium nitrate (AN) oxidizer and a glycidyl azide polymer (GAP). Apart from developing a propellant with good energetic performance, improved safety and low observables, the goal was to obtain a propellant having an exhaust with few harmful emissions. This propellant has now been extensively tested, including the firings of several 70 mm diameter motors, four 200 mm diameter motors, small ballistic test motors inside a closed smoke chamber, and closed bomb tests. Estimates of the exhaust gas composition have been done using a thermochemical equilibrium computer code, and are supported by motor performance data and infrared emission spectra. The smoke chamber firings include mass extinction coefficient measurements of the exhaust smoke, derived from transmissometer data at the visible and 2-14 micron wavelengths. The closed bomb tests provided gas samples for Fourier transform infrared (FTIR) spectrometry and gas chromatography analysis of post-combustion exhaust products. Overall, the results indicated that the combustion of GAP/AN propellants produce exhaust emissions that are less harmful to the environment than those produced by ammonium perchlorate-based propellants. However, mainly because of the presence of zinc oxide in the AN, solid particulates in the exhaust form more primary smoke than a minimum smoke or reduced smoke propellant.

ronmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 7 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche; Original contains color illustrations

Ammonium nitrate (AN) is the base component of a low pollutant propellant, composed by polyurethane (PU) binder, based in hydroxyl terminated polybutadiene (HTPB), a plasticizer (DOA) and a curing agent (IPDI). The impossibility of burning a pure AN-PU propellant of AN concentration of 80 percent leads to find an additive component in order to increase thermal insulation and decrease the global initial density. Glass microballoons (GMB) have these properties and can be assumed as inert in combustion processes. AN-PU-GMB compositions, with AN concentrations from 80 to 90 percent, keeping constant 4 percent of GMB, were tested. Theoretical predictions of combustion pollutants were performed using THOR code, assuming thermodynamic equilibrium of combustion products for the minimum value of Gibbs free energy. Predictions shows negligible NO₂ concentrations. CO emissions were more important than NO, in a good agreement with classic kinetic models. Experimental combustion samples were tested in a steel closed explosion chamber of 17 m(exp 3). They can be heated in the cases where it was not observed self sustained combustion. The real extinction of propellant of AN concentration of 80 percent, without GMB, was observed. A transition situation was verified in this composition with GMB. The combustion process of AN-PU-GMB, with AN concentrations of 83 percent, show heterogeneities, but seems to be relatively stable. Measured combustion temperatures for AN-PU-GMB with AN concentrations of 83 percent were near 1050 K. Measured values of combustion residues were always less than 3 percent of initial mass. The exhaust gas system is connected to a NO, CO, CO₂, CH₄ gas analyzers by IR spectroscopy. Measured concentrations of combustion products, corrected by the dilution factor, show very reliable results. For self sustained combustion, measured CO concentrations were higher than NO. In the other cases, NO concentrations being higher than CO, seems to indicate a pyrolysis regime. CO₂ and NO were higher than the predicted values. The obtained results prove the validity of test procedures and show the existence of self sustained combustion, at atmospheric pressure, of AN-PU-GMB with AN concentrations of 83 percent.

Franco, P., Delegation Generale de l'Armement, France; Guemigou, J., Office National d'Etudes et de Recherches Aeronautiques, France; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 12 p; In French; See also 19960008937; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The shock wave and the high level acoustic waves emitted during the shooting of a missile or a rocket driven by an engine at very short time of combustion (10 ms) can involve a risk of damage to hearing. For these reasons, a number of tools were adapted, usable at the stages of design or evaluation of the project. Thus, in the case of the shootings in free field, an semi-empirical model was developed. This model is based on a model of total explosion to address the generation and the propagation of shock waves generated by an isotropic and instantaneous release of energy. It was then adapted to the case of the engines, starting from results representing a systematic variation of the parameters of design. Lastly, for the shootings simulating the combat in urban area, an experimental study made it possible to specify the mechanisms of formation and reflection of the shock waves on the walls. In addition, a number of tests, according to an experi-

28 PROPELLANTS AND FUELS

mental design utilizing various characteristics of engines and organization of closed space, made it possible to develop estimated rules and abaci.

Molten Salt Oxidation (MSO) is a safe and environmentally acceptable technology for the disposal of energetic waste materials. Initial experiments carried out more than 20 years ago have been supplemented recently with additional work and process improvements. Destruction of energetic materials is nearly quantitative under the current design conditions. The applicability to specialized ordnance wastes is currently under study. These wastes contain a series of chemical elements that are inappropriate to feed to more conventional destruction devices such as incinerators.

A COMPLETE RESOURCE RECOVERY SYSTEM FOR SOLID ROCKET PROPELLANTS

Biagioni, Joseph R., Jr., Aerojet-General Corp., USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 6 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Open burn and open detonation (OB/OD) are currently the methods of choice for disposal of Class 1.1 and Class 1.3 explosive materials. OB/OD methods dispose of the combustion by-products through dispersal into the air and the burial of any residual ash with no recovery of materials other than possibly scrap metal. This paper describes a system which controls emissions to regulatory requirements or below, recovers materials for reuse or recycling, and is designed to be an environmentally acceptable alternative to OB/OD. This three step process removes the energetic material from its container using high pressure water; desensitizes the removed material, making it suitable for thermal treatment; and then disposes of the remaining material in a specially designed incineration system. Test operations completed to date using Class 1.3 solid rocket propellant have demonstrated that this process can recover approximately 90 percent of the starting mass, providing revenue to offset the cost of operation. Recovered materials were ammonium perchlorate (70 percent) and aluminum oxide (20 percent) in these tests. The waste stream is the 25 percent salt solution from the caustic scrubbers which amounts to approximately one gallon (3.8 cu dm) per 250 pounds (113 kg) of material thermally treated. All tests have been conducted under the auspices of research, development and demonstration permits granted by federal, state, and local agencies. System development has proceeded along a logical course consisting of equipment development, worst case testing, and optimization. A fully permitted facility is planned to be operational in 1995.

RECLAIMED AND VIRGIN AMMONIUM PERCHLORATE VARIATIONS AND HOW THEY AFFECT SOLID PROPELLANT PROPERTIES

Durham, S. E., Phillips Lab., USA; Schwartz, D. F., Phillips Lab., USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 17 p; In English; See also 19960008937; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Ammonium perchlorate (AP) reclaimed using the water dissolving technique developed by Thiokol Corporation was compared with the two U.S. manufactured AP's in a polybutadiene-acrylic acidacrylonitrile terpolymer (PBAN) propellant formulation. The reclaimed AP was directly substituted for the virgin materials and natural variances for the propellant mixes were established in the areas of processing, mechanics, and ballistics. The PBAN propellant formulations were scaled up to the 30-gallon mix size and 70-pound Ballistic Test & Evaluation System (BATES) Motors were cast and fired. In addition an 800-pound Super BATES motor was fired. Analyses of the reclaimed and virgin AP samples were performed to identify the chemical properties' variabilities. Results proved that reclaimed AP has the potential to be reused in the solid-rocket-motor industry.

CRITICAL FLUID DEMILITARIZATION AND INGREDIENT RECLAMATION TECHNOLOGY

Morgan, Mark E., Hercules Aerospace Co., USA; Mitchell, Donald H., Hercules Aerospace Co., USA; Stevens, Phil M., Hercules Aerospace Co., USA; Melvin, William S., Army Missile Command, USA; Schirk, Peter G., Rust International, USA; Manar, Otis J., Rust International, USA; Rizzardi, Ned W., Army Corps., USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 11 p; In English; See also 19960008937; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The Department of Defense has a tactical requirement to develop alternative technologies to dispose of large numbers of solid rocket motors without harming the environment. Research efforts conducted at the bench-scale have successfully demonstrated the advantages of the U.S. Army Missile Command (MICOM) critical fluid technology for safe and efficient demilitarization of solid rocket motors. This method has been successfully used to recover valuable ingredients, such as cyclotetramethylenetetranitramine (HMX), cyclotrimethylenetrinitramine (RDX), ammonium perchlorate (AP), and aluminum (AL)/binder, from tactical and strategic Class 1.1 and 1.3 solid propellants. The process uses liquid ammonia for ingredient extraction and recovery. Under an Army-sponsored effort, Hercules Aerospace Company and Rust International have been awarded a contract to design and build a pilot plant test facility, and to demonstrate this demilitarization process on Class 1.1 and Class 1.3 solid rocket motors.

Technical trends in the design of explosives for mining, quarrying and construction have for the last twenty-five years been towards a reduction in the presence of chemical sensitizers. Most recent formulations for blasting have eliminated chemical or high explosive sensitizers altogether. These developments brought benefits of lower E material costs and increased safety in manufacture and use. With the availability of huge quantities of military explosives and propellants from cold war stockpiles now a reality, the industry has to consider what commercial and technical impact these military surpluses will have on existing and new markets, and on the products which are offered for a wide range of field applications. The paper discusses features of available surplus energetic materials which must be considered when designing into civil explosives products and the product characteristics necessary for successful field application. The processes chosen to determine the safety of manufacturing and use are explained and ICI experience in supplying to the market is described.

REDUCED HAZARD CHEMICALS FOR SOLID ROCKET MOTOR PRODUCTION

Caddy, Larry A., NASA Marshall Space Flight Center, USA; Bowman, Ross, Thiokol Corp., USA; Richards, Rex A., Thiokol Corp., USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 11 p; In English; See also 19960008937; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche; Original contains color illustrations

During the last three years, the NASA/Thiokol/industry team has developed and started implementation of an environmentally sound manufacturing plan for the continued production of solid rocket motors. NASA Marshall Space Flight Center (MSFC) and Thiokol Corporation have worked with other industry representatives and the U.S. Environmental Protection Agency (EPA) to prepare a comprehensive plan to eliminate all ozone depleting chemicals from manufacturing processes and reduce the use of other hazardous materials used to produce the space shuttle reusable solid rocket motors. The team used a classical approach for problem-solving combined with a creative synthesis of new approaches to attack this challenge.

PRIORITIZATION METHODOLOGY FOR CHEMICAL REPLACEMENT

Goldberg, Ben, NASA Marshall Space Flight Center, USA; Cruik, Wendy, NASA Marshall Space Flight Center, USA; Schutzenhofer, Scott, NASA Marshall Space Flight Center, USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 12 p; In English; See also 19960008937; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

This methodology serves to define a system for effective prioritization of efforts required to develop replacement technologies mandated by imposed and forecast legislation. The methodology used is a semi quantitative approach derived from quality function deployment techniques (QFD Matrix). QFD is a conceptual map that provides a method of transforming customer wants and needs into quantitative engineering terms. This methodology aims to weight the full environmental, cost, safety, reliability, and programmatic implications of replacement technology development to allow appropriate identification of viable candidates and programmatic alternatives.

BIODEGRADATION OF ENERGETIC COMPOUNDS: APPLICATION TO SITE RESTORATION

Thiboutot, S., Defence Research Establishment Valcartier, Canada; Lavigne, J., Defence Research Establishment Valcartier, Canada; Ampleman, G., Defence Research Establishment Valcartier, Canada; Richer, G., Defence Research Establishment Valcartier, Canada; Lavertu, R., Defence Research Establishment Valcartier, Canada; Hawari, J., National Research Council of Canada, Canada; Greer, C., National Research Council of Canada, Canada; Rho, D., National Research Council of Canada, Canada; Jones, A., National Research Council of Canada, Canada; Renoux, A., National Research Council of Canada, Canada; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 6 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

A multidisciplinary approach involving chemistry, microbiology, ecotoxicology and bioengineering has been undertaken in a joint effort involving the Defence Research Establishment, Valcartier of National Defence Canada (DREV/DND) and the Biotechnology Research Institute of the National Research Council of Canada (BRI/NRC). The aim of this joint collaboration is to study the bioremediation of soils contaminated with energetic compounds such as RDX, TNT, NC and GAP. Contaminated sites were sampled and analyzed for the presence of TNT, RDX and NC. Modified EPA SW 846 Method 8330 was used for the determination of RDX and TNT. As expected, the method was found accurate (greater than or equal to 90 percent recovery), precise (relative deviation standard less than or equal to 2 percent) and sensitive (detection limit less than or equal to 0.5 mg/Kg) over a range of concentration from 0.5 to 20,000 mg/Kg of soil dry weight. Labeled - C-14 energetic compounds were synthesized to monitor their biodegradation. Contaminated soils were screened for microorganisms having the ability to mineralize energetic compounds. Bacteria were isolated from RDX contaminated soils based on their ability to use RDX as the sole source of nitrogen under aerobic conditions when amended with a carbon source. Using C-14 labeled RDX, the ability of these isolates to mineralize RDX in liquid medium was verified. Laboratory-scale studies using the isolates to bioremediate RDX contaminated soils indicate that bioaugmentation enhances the rate and extent of RDX biodegradation. TNT contaminated soils exhibited concentration dependent C-14-TNT mineralization activity. GAP is a relatively new energetic compound and might not yet be found as a soil contaminant. However, a soil sampled on a burning range showed some C-14-GAP mineralization activity. NC mineralization studies are planned in the near future.

EVALUATION OF ENVIRONMENTALLY ACCEPTABLE CLEANERS AS REPLACEMENTS FOR METHYL ETHYL KETONE AND 1,1,1 TRICHLOROETHANE IN SOLID ROCKET MOTOR PRODUCTION AND MAINTENANCE APPLICATIONS

Harrison, A. C., Aerojet-General Corp., USA; Marlow, M. E., Aerojet-General Corp., USA; Levi, L. D., Aerojet-General Corp., USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 6 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The use of 1,1,1 trichloroethane (TCA) will be restricted and ultimately prohibited under the U.S. Clean Air Act and the Montreal Protocol. Use of methyl ethyl ketone (MEK) is currently being restricted by various state air quality districts in California and across the USA. Used widely in the production of composite, metallic, and polymeric components as cleaning solvents, TCA and MEK have long been accepted as diverse and effective solvents by many manufacturers. Therefore, evaluation of potential TCA and MEK replacements requires numerous application considerations, ranging from simple

hardware and tooling cleanup to pre-bond cleaning preparation of critical bonds. This test program evaluates a wide variety of potential solvent replacements within this wide range of common applications.

FINDING AN ENVIRONMENTALLY ACCEPTABLE REPLACEMENT FOR FREON 114B2 (HALON 2402) THAT MEETS MINUTEMAN LITVC PERFORMANCE CRITERIA

Shell, Vaughn, Aerojet-General Corp., USA; Harrison, Anthony, Aerojet-General Corp., USA; Nimitz, Jon, Environmental Technology and Education Consultants, USA; AGARD, Environmental Aspects of Rocket and Gun Propulsion; Feb 1, 1995, 8 p; In English; See also 19960008937; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Freon 114B2 (Halon 2402) is injected into the hot gas exhaust stream of the Minuteman Second Stage solid propellant rocket motor nozzle to provide thrust vector control. In response to environmental concerns, specifically ozone depletion, the USA Air Force has established a program to find and qualify a replacement for Freon 114B2. This program is currently approaching three years of age. Phase 1 of the program consisting of studies and analyses to identify the most promising candidates followed by laboratory testing and full scale motor tests to further screen the candidates down to a single selection (perfluorohexane) has been successfully completed. Phase 2 of the program consisting of qualification firings is scheduled for the latter part of this year and next year.

Ground testing of bipropellant rocket engines with storable propellants demands for adequate test facility concepts to fulfill the needs with respect to health hazards and safety aspects. The general properties and handling instructions for the latest most important hypergolic propellants are reviewed. For a 20 - 30 kN engine to be tested at sea level conditions with the hypergolic propellant, type Monomethyl Hydrazine (MMH) and Nitrogen Tetroxide (N₂O₄), test facility lay-out criteria are presented for two test positions. Design concepts and test facility handling during propellant loading/deloading and hot run phase are described for an engine.

The Propulsion and Energetics Panel Symposium on Service Life of Solid Propellant Motors was held from 10-14 May 1996, in Athens, Greece. It dealt with the methods of extending and predicting service life of solid propellant systems for rockets, gas generators and guns. It also dealt with shelf life under varying conditions. This defence-specific symposium was aimed at improving system reliability, safety and cost. There were five sessions (43 papers) and a keynote address: Chemical and Physical Aging Mechanisms; Non-Destructive Test Methods; Gun Propellants; Methodologies and Techniques for Determining Service Life; Application of the Service Life Methodology and Techniques to Rocket Motor Systems.

The objective of this work was to develop a reliable and safe method, for the accelerated aging, of propellants at different known relative humidities. Safety testing, nitrate ester content, and stabilizer levels were monitored. The safety testing was completed to ensure that all of the samples were safe to handle and store and to determine if aging had any effect on the propellants sensitivity to impact, friction and electrostatic discharge.

The relatively low bond energy of the energetic groups of explosives, typical values are between 150 kJ/mol and 250 kJ/mol, together with frequently occurring low values of the activation energies, between 90 kJ/mol and 200 kJ/mol, lead to an increase in the rate of aging in the case of energetic substances when compared to chemical substances such as toluene and heptane, which are more stable. The activation energies for physical and physical-chemical aging can be even lower, typical values for the migration of plasticizers, phlegmatizers (deterrents), and burning catalysts are about 50 kJ/mol to 100 kJ/mol. The aging of gun propellants (GPs) and solid rocket propellants (RPs) expresses itself in many quantities and properties: in chemical properties such as mean molar masses of polymers, degree of cross-linking, content of stabilizers, antioxidants and plasticizers, in mechanical properties such as tensile strength, strain at break, compressive strength, elasticity and shear modulus, glass transition temperature and embrittlement temperature, in "composite values" such as specific impulse, burning rate, ignition delay, vivacity and

muzzle velocity. As aging can only be slowed down by means of stabilizers and not really stopped, the specified properties of GPs and RPs are altered with time-temperature stresses. This makes the substances dangerous whilst in storage and when in use. The hazards are known as spontaneous ignition, breech blow and motor explosion. But also the designed performance data of a gun or a rocket are changed, which expresses itself in a lowering of the muzzle velocity, bad target picture and in the case of RP in a non-controlled burning rate. Therefore it is necessary to quantify aging processes in order to be able to specify after what time-temperature stresses the properties required still lie within the range of tolerance that means to make a reliable prediction. The quantification is done using mathematical descriptions of the changes in the values of properties, which are connected to the relevant aging processes, as a function of time and temperature. If necessary also further variables such as humidity and oxygen are included. The description must achieve a separation between time and temperature so that a prediction for other time-temperature values becomes possible. This procedure will be described using a number of examples: migration of burning catalysts, decrease in the mean molar masses M_n , M_w and M_z of nitrocellulose in the propellants, stabilizer consumption, decrease of mechanical properties, mass loss, and heat generation, the latter two also with autocatalysis.

The aging study methodology is joined to the propellant formulation researches from the aging behavior optimization at laboratory scale to the characterization. The characterizations are realized on case-bonded mock-ups which are subjected to thermal cycles designed to accelerate the aging produced by environment encountered in airborne applications. 2 months cycle is expected to simulate 1 year of service life. The mock-ups are dissected after 1 or 2 years. The testing are mainly directed at looking at changes in propellant and bonding mechanical properties. The results may be used to assess the service life of a rocket motor loaded with the propellant tested. The experimentations conducted during 1 year on a reduced-smoke propellant containing Butacene (registered trademark) as burn rate catalyst show the good aging behavior of this composition.

In June of 1990, the USA Secretary of Defense banned Short Range Attack Missile-A (SRAM-A) from being loaded aboard the B-52, B-1, and F111 bombers. He was concerned that the ferrocene-containing rocket motors could inadvertently detonate and spread plutonium dust over large areas. Tests were conducted to ascertain that the motors were safe enough to be shipped to a facility where they could be properly disposed. The data and methods used to handle the

propellant are described herein and may be of interest to anyone contemplating the handling, storing, or formulating of ferrocene-based propellants.

A study has been conducted to know the effect of aging over mechanical and ballistic properties of composite propellants. Natural aging tests and accelerated aging tests at elevated temperatures have been performed for five different formulations of rocket propellants; the aging process has an effect on mechanical, chemical and ballistic properties. Measurements of tensile, viscoelastic and ballistic properties are reported. A relationship between shore A hardness and tensile properties has been established. Application of a theoretical prediction model has permitted conclusions to be drawn about service life, effect of environmental conditions and propellant mechanical requirements.

The factors which need to be considered in the aging, life prediction and life extension of composite propellant motors are considered. The chemical and physical changes which can occur are described, with particular reference to compositions based on hydroxy-terminated polybutadiene binders. The importance of atmospheric oxygen in the process is emphasized, and the factors determining the rate of the critical aging processes are discussed. Accelerated aging experiments are described, and the information necessary for extrapolation of such data to service temperatures is considered. In order to discuss service lifetimes, it is necessary to have reliable data describing the service environment. The effect of environment, such as temperature, on propellant aging is considered. The importance of motor design, and its tolerance to changes due to aging, is discussed, and simple measures which can be taken to extend motor service life are described.

LIFE TIME ASSESSMENT AND STABILITY OF AN/GAP PROPELLANTS

Bohn, Manfred A., Fraunhofer-Inst. fuer Chemische Technologie, Germany; Boehnlein-Mauss, Jutta, Fraunhofer-Inst. fuer Chemische Technologie, Germany; Menke, Klaus, Fraunhofer-Inst. fuer Chemische Technologie, Germany; May 1997; 16p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

If the ingredients and their chemical properties are considered, propellants based on ammonium nitrate, GAP binder and nitrate ester plasticizers are a challenge to achieve good chemical stability and a sufficient life time. This contribution gives a short overview about the chemical stability of propellant formulations with pure AN (so-called SCAN with less than 0.04 mass% water content) and phase stabilized AN (PSAN) in AN/GAP/TMETN/BTTN-based formulations and with a new burn rate modifier based on mixed molybdenum/vanadium oxides called MOVO. Stabilizer consumption, mass loss, cube crack thermal cycling and other aging tests were performed with distinctive formulations. It is shown that phase stabilizing metal complexes for AN as well as BTTN deteriorate the chemical stability and shorten the life time of the propellants. DPA and a mixture of MNA/2NDPA prove to be suitable stabilizers. Stabilizer consumption is described with an improved kinetic formulation based on a combination of the reactions of first and zero order. For the prediction of life times with mass loss as function of time and temperature an autocatalytic rate equation is used. As a result of the development a propellant formulation was found with medium performance ($I(\text{SP}) = 229 \text{ s at } 7 \text{ MPa}$) based on pure AN in AN/GAP/TMETN with MOVO burn rate modifier, which has satisfying values for chemical stability and a sufficient life time. The propellant will meet the applicational profiles of a temperate climate.

CHARACTERIZATION OF THE DEGRADATION OF THE POLYMER BINDER IN GAP-BASED PROPELLANTS

Desilets, S., Defence Research Establishment Valcartier, Canada; Perreault, F., Defence Research Establishment Valcartier, Canada; May 1997; 6p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Reliability assessment for composite propellants call for effective shelf-life predicting tools, implying the existence of appropriate accelerated aging procedures and of quantitative methods for the characterization of the degradation process. Ideally, one would like to investigate stabilizer depletion as well as the mechanical integrity of the polymeric network used as the binder. There are many available methods that can be combined to achieve this goal. In the present work, a comparative study of two of these methods has been performed. The first procedure makes use of FTIR spectroscopy to characterize the binder's degradation and of HPLC to follow stabilizer depletion. The other method based on ^1H -NMR spectroscopy allows the measurement of the polymer network degradation, the depletion of the stabilizer and the loss of plasticizer in a single step. Finally, the pros and cons of both procedures have been evaluated from the analysis of experimental data related to the accelerated aging at 40, 60 and 80 C of GAP-based composite propellant formulations.

After manufacturing, missiles may precociously be aged due to bad storage conditions or/and thermal cycling i.e. repetitive captive flights. This precocious aging can generate disbands at the various interfaces of the rocket structure or modification of the mechanical properties of the propellant. This defect or modification can be dangerous for the plane when firing the missile. A study began to build a system usable on site which allows one to know if the missile can be fired or not. The present paper gives the status of work of this study. Derived from text

It is essential that the mechanical properties of a propellant grain are assessed during its service life to ensure that the grain has an adequate margin of safety to survive future deployment loads. The physical properties of the propellant should also be sufficient to withstand the final loading, motor pressurization on ignition. Each propellant grain can be considered unique by virtue of its manufacturing processing and its subsequent service history. In the past, it was practice to treat the population of a particular type of motor as being uniform in properties and, as such, individual motors were dissected to determine the physical properties. The obvious disadvantage to this method was that the rocket motor grain was destroyed. What was realized, however, was that the motor that had been dissected may not have been truly representative of the group to which it belonged. This dilemma was resolved by the introduction of a non-destructive test which could be applied to all the motors in the group. The Penetrometer and its usage is described within this paper.

Within solid propellant rocket motors there sometimes exist separations or bond defects between case and liner (insulation made of elastic polymer) or between liner and propellant. This paper demonstrates that separations or bond defects can be detected by thermography. Till now the smallest defects that could be detected had a diameter of 20 mm and a separation of 0.05 mm.

Mechanical and chemical properties of a particle filled elastomeric polymer, such as a solid rocket propellant, may change with age and contribute to the degradation of motor performance. Nondestructive evaluation (NDE) methods have been developed and tested to characterize changes in materials caused by chemical aging processes. Ultrasonic methods have been evaluated for monitoring changes in bulk propellant properties including particle dewet strength and bulk elastic properties. Theory of operation and test results for each method are reported. Some methods are applicable to full-scale rocket motors and others are intended for laboratory use to provide data for calibration and understanding.

The assessment of the safe and nominal operability of solid rocket motors after a long period in storage or in operational carriers is a constant concern of users. Whilst numerous techniques have been proposed for that purpose, none has proved to be fully satisfactory. Traditional X-ray analysis provides useful, but insufficient results. High density computed tomography, a powerful non-invasive means of investigation, has become over the last decade, thanks to its unique performance, the major tool for shelf life assessment, especially in the U.S.A. DOD sponsored research has been carried out in this field in France. This paper summarizes the results obtained regarding the specific equipment (sensors, measurements) and the performances measured. From the results available, tomographic images can be considered as providing an identity card of the motor, enabling its monitoring in time.

The Indian Head Division of the Naval Surface Warfare Center, in Indian Head, Maryland, U.S.A., has an ultrasonic system capable of volumetrically evaluating small diameter rocket motor propellant grains. The ultrasonic system and the evaluation technique described in this paper are used to inspect a specific weapon system component. With minor modifications the system and technique can be used to inspect a wide variety of extruded rocket motor propellant grains. In this evaluation the propellant grains are extruded and tape wrapped prior to inspection. The grains may be evaluated however, in an as extruded condition. The grains are approximately 2.6 inches in diameter, approximately 3 feet in length and contain an eight point star bore. The star bore, formed during the extrusion process, is made by forcing a propellant blank or carpet roll through a cross shaped center stake support. The center stake support sections the blank into four quadrants. With a combination of pressure, speed, vacuum and temperature the four quadrants are extruded down onto the eight pointed star

shaped center stake. The extrusion process parameters are very critical and any variation in temperature, speed, pressure or vacuum can result in the introduction of discontinuities.

The USA Army, the U.S. Navy, and the U.S. Marine Corps each conduct safety surveillance programs to monitor the stability of their gun propellants that are nitrate ester-based. This paper provides an overview of the efforts from those programs. The paper discusses the rationale behind current test programs and test techniques. The paper provides some "lessons learned" from previous techniques and provides some information on the efforts of the programs during the past five years.

FORMER AND MODERN METHODS FOR THE DETERMINATION OF THE SERVICE LIFE OF ROCKET PROPELLANTS

Holl, G., Bundesinstitut fuer Chemisch-Technische Untersuchungen, Germany; Wilker, S., Bundesinstitut fuer Chemisch-Technische Untersuchungen, Germany; Kaiser, M., Bundesinstitut fuer Chemisch-Technische Untersuchungen, Germany; Guillaume, P., Patscentre Benelux Clermont S.A., Belgium; May 1997; 14p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Different methods that are nowadays used to determine the service life of a propellant are briefly introduced and discussed. In the second part selected results of classical high temperature tests, heat flow calorimetry, stabilizer consumption and molecular mass depletion as well as NMR experiments are presented. In summary it can be stated, that only a combination of many different methods allow to make predictions of the ballistic life time of a propellant. To do this still a huge amount of experiments must be done to define the "allowable" limits of energy loss, of stabilizer consumption, of migration processes or changes in mechanical properties.

France has devised in 1975 a stability test based on decrease of stabilizer after 6 weeks at 50 C. The aim of this test is to predict if a new propellant will give a good guarantee of conservation. The test has been used for 20 years on single base propellants made with diphenylamine. Now it's possible to prove the validity of this test by studying

the results obtained after natural aging and results obtained with this test. We can also show that tests, based on artificial aging at higher temperatures, are not representative.

AGEING BEHAVIOUR OF PROPELLANTS DETERMINED BY MASS LOSS, HEAT GENERATION, STABILIZER CONSUMPTION AND MOLAR MASS DECREASE

Volk, Fred, Fraunhofer-Inst. fuer Chemische Technologie, Germany; Bohn, Manfred A., Fraunhofer-Inst. fuer Chemische Technologie, Germany; May 1997; 14p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

During the service life of nitric acid ester based propellants a consumption of stabilizer and a degradation of the mean molar (molecular) masses such as number average M_n , mass average M_w and Z-average M_z of the nitrocellulose occur due to decomposition reactions. Therefore the chemical and mechanical properties of the propellants are changed and the safe service life and the safe storage time, the so-called lifetimes, are limited. In order to predict the lifetimes one needs to measure properties P , which are changed by the decomposition reactions in the propellant and which can be determined with good accuracy as a function of time and temperature, if necessary also in dependence of further variables. For propellants consisting of nitric acid esters, stabilizer consumption, molar mass degradation and mass loss are very suitable properties. Heat generation measured by heat flux microcalorimeters is an assessment of the momentary reaction rate. The stabilizer content was measured by reversed-phase high performance liquid chromatography (HPLC), the molar mass degradation by gel permeation chromatography (GPC), the heat generation was determined by a microcalorimeter and the mass loss with an analytical balance. For the evaluation of the experimental data kinetic models are used. The molar mass decrease is reproduced very well by a model, which assumes a statistical chain scission by the decomposition of chain elements. Stabilizer consumption is described with two models, one is based on a reaction of first order, the other one is a combination of first and zero order reactions. With these kinetic descriptions lifetime predictions are made. This is done for single temperatures and for three temperature-time profiles, two from STANAG 2895 and one from the industry. The mass loss and the heat generation measurements show the autocatalytic acceleration of the decomposition reactions for some gun propellants and for nitrocellulose and corresponding autocatalytic kinetic models are used for the mathematical description of the data. The pre-autocatalytic aging can be evaluated by a reaction of zero order and results are given for the heat generation of a double and a triple base gun propellant. The linear mass loss increase is compared between five German gun propellants (GP) and the energetic binder GAP. The gun propellants are: single base A5020, single base K503, single base (with DNT) CD5240 (US M6), double base L5460 (US JA2) and triple base KN6540 (US M30).

LOVA PROPELLANT AGING: EFFECT OF RESIDUAL SOLVENT

Pesce-Rodriguez, R. A., Army Research Lab., USA; Fifer, R. A., Army Research Lab., USA; May 1997; 10p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

An investigation of LOVA propellant aging was performed to identify the cause of stabilization periods in certain propellant lots. Two important observations were made: (1) the level of residual solvent in propellant grains slowly decreases while in storage; and (2) during the drying process and while the grains are in storage in storage, plasticizer "co-migrates" with solvent, resulting in plasticizer accumulation at grain surfaces. It was also observed that while in storage, residual

solvent may be oxidized to generate organic acids. Based on these results, it is proposed that stabilization periods result from processes related to migration, evaporation, and oxidation of residual solvent.

This paper presents the works carried out by SNPE to meet the specifications (chemical stability, ballistic stability at high temperature, lifetime) required for a medium caliber ammunition for aircraft. The behavior of industrial gun propellant has been improved by optimizing the properties of the nitrocellulosic matrix. Yet this solution is limited because of the chemical stability of nitrocellulose. So, SNPE has proposed composite gun propellants based on an inert or energetic binder filled with nitramine (RDX). Their thermal properties and their lifetime will be discussed and compared to those of single base gun propellants.

This paper describes the work done at DREV to develop modern methods of monitoring the chemical stability and remaining safe life of gun powders stocked by the Canadian Forces (CF). It begins with the rationale behind the choice of high-performance liquid chromatography (HPLC), as well as the criteria the HPLC methods must meet. This is followed by a description of the development of two fast, reliable and efficient methods. Finally, the role of N-NO-DPA as a stabilizer and the sentencing criteria are discussed.

At the 12th meeting of The Technical Cooperation Program (TTCP), Panel W-4, Propulsion Technology, participants from the USA and the United Kingdom jointly proposed a collaborative program within TTCP. The aims of this program were to improve experimental methods and attempt to validate current predictive service life methodologies. A decision was taken to evaluate solid rocket motor propellants containing HTPB propellants. All the participants fielded motors that were instrumented and then subjected them to agreed programs of work. In September 1988, formal approval was received and the collaborative program became Key Technical Area 14 (KTA-14). Canada, Australia, the UK and the US all fielded motors for the program. This paper outlines some of the results from the work carried out in the UK by Royal Ordnance Rocket Motors and the Defense Research Agency Fort Halstead.

MINIATURE SENSOR FOR MEASURING SOLID GRAIN ROCKET MOTOR CASE BOND STRESS

Chelner, Herb, Micron Instruments, USA; Buswell, J., Defence Research Agency, UK; May 1997; 12p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Solid propellant normal bond stress profiles are calculated and used in the predication of motor service and storage life. Bond stresses are calculated instead of measured due to the belief that making the measurement is difficult and available sensors too inaccurate. Recent developments in stress measurement technology and instrumentation has changed that situation completely. This reported work has resulted in the design of a miniature sensor with improved accuracy and stability and which is more easily installed in rocket motors with minimal effect on the grain stress distribution. The design goal for thermal hysteresis, when thermally cycled between -45 C to +65 C was 7 kPa (1 psi). Sensors with less than 3 kPa (± 0.5 psi) were produced but the yield needs to be improved. The long term stability design goal of 7 kPa (1.0 psi) per year was exceeded. The average drift of all sensors tested was less than 5 kPa (0.7 psi) per year with many sensors drifting less than 2 kPa (0.25 psi) per year. For ease of installation the low flat miniature profile with a diameter of 7.6 mm and a 2.0 mm thickness fits easily into the motor lining or may be bonded to the case wall. A 1.0 mm hole is required for the 5 conductor cable which can be disconnected from the remote bridge completion package for installation and routing without soldering. The remote bridge completion housing comes complete with water seals on the cable, top cover and electrical connector.

VERIFICATION OF THE SWANSON NONLINEAR THERMO-VISCOELASTIC MODEL USING STRESS GAGE TECHNOLOGY
 Wong, F. C., Defence Research Establishment Valcartier, Canada; Firmin, A., H. G. Engineering Ltd., Canada; Liu, Y. C., H. G. Engineering Ltd., Canada; May 1997; 14p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Solid propellants must function as a structural member as well as an energy source. They must deform without failing under thermal, acceleration and pressurization conditions. Structural failure by cracking is usually catastrophic since the advancing flame front propagates into any exposed surface. Therefore, the ability to predict the stress-strain state of a propellant is critical to the establishment of a motor's operational limits. Stress prediction for propellants is complicated by the fact that this material exhibits nonlinear viscoelastic characteristics. This paper summarizes the development of a modified Swanson constitutive model for use in the finite element program ABAQUS. Predictions of propellant behavior for three uniaxial test cases and one three-dimensional test case are made and compared to experimental results. The uniaxial test cases cover the propellant's stress response to straining-cooling and thermal shock environments. Measurements from an instrumented rocket motor placed in a thermal shock environment provide the data for evaluating the three-dimensional prediction capabilities of the ABAQUS implementation. It will be shown that the modified Swanson model can predict nonlinear viscoelastic behavior correctly but to be used for solid rocket motor service life methodologies, the model still requires some calibration using in-situ measurements from an instrumented rocket motor.

Rocket motor service life predictions have always been compromised by the nonlinear viscoelastic behavior of the highly filled solid propellants. These nonlinearities include damage and rehealing which are dependent on the thermal loading histories and stress axialities in the grain. Recent work to eliminate some of these analytic uncertainties has led to the development of improved experimental stress analysis methods based on actual measured rocket motor bond stresses. A third generation of miniature bond line stress sensors have been fabricated which have increased accuracy, stability and can be used for in-situ health monitoring of tactical motors. The use of these units in service life programs has already measured the time dependency and nonlinearities which are exhibited in typical laboratory tests on solid propellants. These measurements can be used to correct the stress analysis output and hence lead to more accurate structural integrity calculations. The major objective of this new technology is the reliable prediction of safe service life giving a more cost effective missile replacement policy.

INSTRUMENTED SERVICE LIFE PROGRAM FOR THE PICTOR ROCKET MOTOR

Ho, S. Y., Defence Science and Technology Organisation, Australia; Ide, K., Defence Science and Technology Organisation, Australia; Macdowell, P., Defence Science and Technology Organisation, Australia; May 1997; 8p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper describes a Solid Propellant Rocket Motor Service Life program conducted at the Aeronautical and Maritime Research Laboratory/ DSTO, which combined a nonlinear viscoelastic analysis of an Australian R&D motor, Pictor, and used miniature embedded stress transducers to validate analysis and/or define the actual stresses in the rocket motor during various thermal loading conditions (thermal shock, thermal cycling, accelerated aging and ambient aging). The measured stresses during solid propellant rocket motor thermal cycling were obtained for comparison with linear elastic/viscoelastic and nonlinear viscoelastic finite element analysis. Measurements are in reasonable agreement with nonlinear viscoelastic analysis for most motor loading conditions. Capabilities for modified Fracture Mechanics and non-linear viscoelastic analysis were incorporated into a commercial general purpose finite element (FE) code, STRAND 6.1. The thermal stresses induced in the motors were modeled using this FE code. The code was also developed to calculate the critical crack length for propagation during thermal transients. Uniaxial and biaxial tension, and bond-in-tension tests were conducted for the failure analysis. Additionally, a modified Fracture Mechanics approach was used to obtain the fracture energy ($G_{sub c}$) as an alternative failure criterion and also to determine the critical crack length for propagation.

Three critical factors were used to determine the Service Life Estimate for a solid rocket motor. First, the material property aging trends over time were evaluated. Second, an accurate structural analysis was performed. In this work, Nonlinear Viscoelastic (NLVE) analysis techniques were used to provide the most accurate assessment of propellant behavior. Finally, a probabilistic approach was applied, incorporating test data, aging trends, and variations of input param-

28 PROPELLANTS AND FUELS

ters to obtain the service life. Development of the approach included an evaluation of various NLVE constitutive theories and their verification in laboratory tests using subscale motors. The approach was applied to a solid rocket motor using 3D NLVE analysis and the probabilistic service life estimate methodology.

The deformation of bonded rubber samples is studied through use of an opto-electrical system, consisting of electronics, optics, and software. The system makes it possible to determine the stress-strain behavior of specimens tested in a tensile tester. Measurements are unique in that detailed localized information becomes available so that particular deformation behavior can be studied. The test series being reported was performed as a design of experiments so that a statistical analysis of variance could be applied to the results. The parameters studied were rubber flexibility, thickness, and order of sample stacking. Sample test data and the complete analysis of variance are presented, resulting in generalized equations for the parameters tested.

An approach of the structural service lifetime problem of solid propellant rocket motors is presented, based on a combination of experimental and theoretical techniques. It includes propellant aging research, monitoring and non-destructive testing of life motors, dissectioning of motors, testing of the propellants, accelerated aging techniques, static firings and computer modeling incorporating aging effects. Typical aging results regarding chemical and mechanical aging of composite propellants are shown. Preliminary lifetime prediction models are used to give insight in the available rest life of a rocket motor. For an accurate lifetime prediction it is important to have insight in the initial propellant properties, aging characteristics, motor design and environmental history of the motor.

PROBABILISTIC SERVICE LIFE PREDICTION FOR SOLID PROPELLANT MOTORS SUBJECTED TO ENVIRONMENTAL THERMAL LOADS

Heller, R. A., Virginia Polytechnic Inst. and State Univ., USA; Thangjitham, S., Virginia Polytechnic Inst. and State Univ., USA; Janajreh, I. M., Michelin Americas Research Corp., USA; May 1997; 12p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Tactical solid propellant rocket motors stored under field conditions are subjected to environmental temperature variations and, as a consequence, to variable thermal stresses. These stresses may, during the service life of the motor, exceed the cumulatively damaged strength of the propellant resulting in cracks that could induce failure upon firing. Because both temperature and material properties are random variables, service life calculations should be based on probabilistic considerations, i.e., motor life is to be terminated when the progressive probability of failure which increases with elapsed time exceeds a predetermined value.

One methodology in common use today for evaluating service life is based on chemical kinetic models quantified by the rate theory of Eyring and the Arrhenius relationship. Techniques employed to accomplish this task may include mechanism studies as well as kinetic evaluation of material property changes. Verification of aging trends and models may be accomplished through motor dissections, plug motors, and excised samples. This methodology and associated techniques will be discussed in depth.

SERVICE LIFE PREDICTION OF SOLID ROCKET PROPELLANT MOTORS STORED IN A RANDOM THERMAL ENVIRONMENT

Margetson, J., Defence Research Consultancy, UK; Wong, F. C., Defence Research Establishment Valcartier, Canada; May 1997; 12p; In English; See also 19970034746; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A service life prediction analysis is developed for solid propellant rocket motors which are stored under statistically varying environmental conditions. Monitoring devices are used to measure the statistically varying stresses and strains which are induced as a result of the statistically varying diurnal and seasonal thermal cycles. A failure probability analysis is used to determine the probability that the statistically varying time dependent stress (strain) exceeds the statistically varying strength (strain capacity) of the propellant. A time dependent failure probability growth relationship is used to determine the time taken for the failure probability to increase to a specified unacceptable level. This time denotes the service life. The probabilistic service life prediction analysis is applied to an instrumented rocket motor stored

at the environmental site at Valcartier, Canada. The results are compared with the service life predictions derived from a deterministic structural analysis approach.

A correlated experiment between stabilizer consumption in the propellant and ballistic properties of a solid rocket motor, which include the same propellant, has been performed. Results have showed that ballistic properties can change substantially before the stabilizer has been consumed. Previously propellant was analyzed and compared with other propellants. These are four homogeneous rocket propellants which were tested to find out stabilizer consumption during two years artificial aging at 50 C. All propellants had a previous natural aging of between 10 and 27 years. Ballistic properties were measured during a series of firings in rocket motor test stand. Propellant samples and solid rocket motor have been subjected to the same aging test.

Descriptions are given of the various NATO standards and specifications for the environmental aspects in the service life cycle. Details are given of the differing climatic and mechanical loads related to the individual elements in the manufacture-to-target sequence within the life cycle of the rocket motor for tactical missiles. Aspects concerning the use of extreme conditions and measured data are related to the storage and operational use phases in the differing life cycles of land, sea and air forces' tactical missiles. The main considerations and limitations during environmental testing programs are discussed. The use of modern methods of data capture and analysis are recommended.

This paper presents two different methods for tactical service life prediction. In the first approach, called Simulated Natural Aging (S.N.A.), the evaluation of aging effects on physical properties and performances of Rocket Motor is performed through specific short time aging programs, simulating long term storage and field conditions. In the second approach, S.N.A. programs are conducted on case bonded Rocket Motors analogs. Dissections provide convenient results used in reliability predictions as a function of aging time. The comparison with reliability requirements makes possible the Rocket Motor service life prediction. The second approach can be used if the main aging risk is identified and if the modelization is possible.

Over three decades ICT and the first author of this paper were engaged in research of the aging behavior of propellants and the life time prediction of rocket propellant grains. In the context of these R + D activities test methods were created or known procedures were improved for special application. These methods were used to predict the service life determination of rocket motors, which were in service for many years in NATO countries. Starting with some definitions about life time the most important physical and chemical aging phenomena for the different propellant types and their influence of the life time of the grain were described and their effects discussed. The knowledge of the time depending on aging behavior will be the fundament of the simulation procedure to evaluate the predicted life time of a system. To safe expenses and time, for the investigations to predict life time a tailoring principle is used. This method collects all stresses which the weapon system has to overcome during the whole future life time, including all pretreatments. Outgoing from these data a tailored simulation will be performed to fix the predicted service life time.

The chemical stabilizer depletion rates of a number of Cast Double Base (CDB) propellants have been investigated by aging at elevated temperatures. New values for the activation energy for par-nitro-N-methylaniline (pNMA) degradation have been calculated for formulations containing both lead and copper based ballistic modifier systems. These have been used to generate predictions of depletion during natural storage of service motors. These predictions were accurate within the limits imposed by the absence of detailed thermal history for the test rounds. Suggestions for future study are made.

Between 1970 and 1980 the SEP conducted many tests allowing one to describe and test the use of composite materials on propulsion systems used for strategic, pre-strategic and tactical missiles. Between 1980 and 1988 the SEP was also involved in the development of propulsion systems for S530D and Mistral missiles. It thus acquired a great deal of experience pertaining to the constraints recorded during the operational life of tactical missile propulsion units. Their consideration in the development of engines allowed them to improve and adjust performance features of materials and architectures for the propulsion systems. In this report we first present the structural assembly method used for the production of S530D and

The purpose of the aging tests is to perform a regular monitoring of the development of the weapon system's performances and characteristics in the course of time in order that performances and the contractual availabilities during the whole lifetime of the system can be guaranteed so as to initiate early enough preservation actions which might become necessary (recycling, manufacture of new equipment) in case life of some equipment should expire before the planned time limit. Three important test and aging categories can make the above monitoring possible: accelerated aging tests; real natural aging tests; and simulated natural aging tests. This conference presents the choice made as well as the principles and the content of the test program considered for the accelerator of an air to surface missile.

Unlike ordinary motors, solid propellants rockets operate only once and for a very short period of time. So, a method able to investigate the behavior of the grain during static firing test is of high interest for the people in charge of the development program especially regarding the following phases: ignition, burning surface Propagation, and defects behavior and motors failure modes. The connection of high speed video camera with real time x ray equipment allows valuable data acquisition during the firing and fulfill the need of direct investigation of the related phenomenon. In this paper some examples are presented, analyzed, and compared with computed simulation.

This invited paper, which was the second oral presentation at the conference, covered the conclusions found by NIAG SG-37 during a one year research of the issues and solutions to furnishing extended air defense capability to NATO and its forces. Key issues diagnosed included: (1) the requirement of a multi-layered defense system that includes space-based defense, aircraft, missiles, and other hardware; (2) the electronics needed for this support; and (3) the materials, propulsion devices, and lethality of the systems. A technological forecast of funding recommendations is included.

The end of the Seventies and beginning of the Eighties showed significant technological developments in ballistic missiles, in particular, impact precision. These improvements caused Western strategists to be concerned with use of ballistic missiles equipped with conventional loads against military objectives (the Pact of Varsovie). The concept of ballistic missile tactical had been born. The ballistic vector, which until this time was marked with a 'strategic' label, was then 'standardized' and has interested a number of countries in the process of its development. The world has just entered the era of the ballistic proliferation. From the very start of the Eighties, the USA and, to a lesser degree, NATO lead studies and reflections concerned with defense against tactical ballistic missiles within a East West framework. From these studies the ATBM (Anti Tactical Ballistic Missile) made its appearance. In spite of the attempts at control, missile proliferation has accelerated and led, towards the end of the Eighties and the beginning of the Nineties, to the awakening of a new risk known as proliferating. The 1991 Gulf War was accelerated in this manner. This conflict also clarified the fact that the ballistic weapon constituted a formidable means of pressure for countries which had it, in spite of the PATRIOT, which demonstrated the feasibility of an active defense

against ballistic missiles, in spite of their limited performances. This present presentation proposes an overall analysis of the ballistic risk and the possible threat which could result from it and examines the means available for protection against this risk by looking further into all the defensive means. This will constitute the main part of the speech. Lastly, we will endeavor to evaluate the difficulties faced by the architects of the DAMB.

SOSIE: A PRAGMATIC APPROACH TO THE SIMULATION OF
BROAD AIR DEFENSE APPLIED TO THE THEATER LEVEL
SOSIE: UNE APPROCHE PRAGMATIQUE DE LA SIMULATION EN
DEFENSE AERIEENNE ELARGIE APPLIQUEE AU NIVEAU DU
THEATRE**

Tanter, A., GIE Cosyde, France; Deas, M., GIE Cosyde, France; AGARD, Guidance and Control for Future Air-Defence Systems; Jan 1, 1995, 8 p; In French; See also 19950025702; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The SOSIE concept rests on an approach consisting of using existing simulation models of various systems and subsystems and automatically integrating them with minimum modifications within a center of simulation. The defense simulation against ballistic missiles on the theater level calls upon three levels of simulation: DIAMS; TACSIT, and SPOOK. DIAMS presents a fine level system simulation of weapon ground-to-air average carry, TACSIT presents a level of site defense (base air for example), and SPOOK deals with the theater level itself. SOSIE enables users to use the same detailed simulators, developed by an originator of weapon systems or information and communications, without having to know in detail the models of the simulation. Envisioned in the future is the integration of other models of simulations relating to the air-to-air combat, in particular, the networks of command, controls and communications.

The benefits of the ATP (Acquisition Tracking and Pointing) assets to TMD (Theater Missile Defense) are that the platform provides high resolution standoff sensors at low cost and can provide sub micro radian tracking and imaging of dynamic targets, active and passive multispectral data and non-cooperative fire control algorithms. The platform is relatively low cost and can be flown from 4-6 times a year for either sensor performance or phenomenology data collection. The process for collecting and certifying the data are in place and available today. During the past decade we have made significant advances in ATP-FC technologies for ballistic missile

defense. The current BMDO ATP assets in general and the HABE testbed in particular can be a key asset in developing TMD weapon systems by providing a means to collect key phenomenology data, test sensor and guidance components, or view and collect data to score test or exercises.

The High Altitude Balloon Experiment demonstration of Acquisition, Tracking, and Pointing (HABE-ATP) is a system built around balloon-borne payload which is carried to a nominal 26-km altitude. The goal is laser tracking thrusting theater and strategic missiles, and then pointing a surrogate laser weapon beam, with performance levels end a timeline traceable to operational laser weapon system requirements. This goal leads to an experiment system design which combines hardware from many technology areas: an optical telescope and IR sensors; an advanced angular inertial reference; a flexible multi-level of actuation digital control system; digital tracking processors which incorporate real-time image analysis and a pulsed, diode-pumped solid state tracking laser. The system components have been selected to meet the overall experiment goals of tracking unmodified boosters at 50- 200 km range. The ATP system on HABE must stabilize and control a relative line of sight between the platform and the unmodified target booster to a 1 microrad accuracy. The angular pointing reference system supports both open loop and closed loop track modes; GPS provides absolute position reference. The control system which positions the line of sight for the ATP system must sequence through accepting a state vector handoff, closed-loop passive IR acquisition, passive IR intermediate fine track, active fine track, and then finally aimpoint determination and maintenance modes. Line of sight stabilization to fine accuracy levels is accomplished by actuating wide bandwidth fast steering mirrors (FSM's). These control loops off-load large-amplitude errors to the outer gimbal in order to remain within the limited angular throw of the FSM's. The SWIR acquisition and MWIR intermediate fine track sensors (both PtSi focal planes) image the signature of the rocket plume. After Hard Body Handover (HBHO), active fine tracking is conducted with a visible focal plane viewing the laser-illuminated target rocket body. The track and fire control performance must be developed to the point that an aimpoint can be selected, maintained, and then track performance scored with a low-power 'surrogate' weapon beam. Extensive instrumentation monitors not only the optical sensors and the video data, but all aspects of each of the experiment subsystems such as the control system, the experiment flight vehicle, and the tracker. Because the system is balloon-borne and recoverable, it is expected to fly many times during its development program.

31 ENGINEERING (GENERAL)

Decision Aids. Each project has developed and continues to refine workstation prototypes. As the technology in these prototypes matures it is used to update and improve an integrated MMA system prototype. This paper is concerned with the integration process and the issues surrounding it. The factors which influenced progress during integration include the use of compatible development platforms and programming languages for the prototypes, and the choice of a host architecture which allows a flexible approach to the MMA architecture. The benefits gained from the integration framework include the ability to develop integrated displays and controls, to evaluate performance and effectiveness metrics, and to investigate the boundaries and interactions between the subsystems.

Paint stripping and repainting of aircraft surfaces are required periodically during the operating lifetime of an aircraft. Historically, paint removal has been achieved using chemical strippers, involving materials which contain toxic components and which create hazardous working conditions. The process generates large amounts of hazardous waste from the chemicals used. Alternative methods for aircraft paint removal are now being investigated within the NATO nations with regard to their environmental safety and effective application. These processes include: Plastic Media Blasting, Wheat Starch Dry Media Blasting, Carbon Dioxide Pellet Blasting, Sodium Bicarbonate Blasting and Thermal Decomposition Methods (Laser, Flash Lamps/Carbon Dioxide). The Lecture Series will review these current state-of-the-art alternative methods with environmental effects and related health hazards, costs, process controls, and more.

With the introduction of strict environmental regulations governing the use and disposal of methylene chloride and phenols, major components of chemical paint strippers, there have been many new environmentally safe and effective methods of paint removal developed. The new methods developed for removing coatings from aircraft and aircraft components include: mechanical methods using abrasive media such as plastic, wheat starch, walnut shells, ice and dry ice, environmentally safe chemical strippers and paint softeners, and optical methods such as lasers and flash lamps. Each method has its advantages and disadvantages, and some have unique applications. For example, mechanical and abrasive methods can damage sensitive surfaces such as composite materials and strict control of blast parameters and conditions are required. Optical methods can be slow, leaving paint residues, and chemical methods may not remove all of the coating or require special coating formulations to be effective. As an introduction to environmentally safe and effective methods of paint removal, this paper is an overview of the various methods available. The purpose of this overview is to introduce the various paint removal methods available.

An attempt is made to group the various processes of paint removal into families. The classifications are distinguished by chemical, mechanical, and thermal phenomena. For each of these phenomena, it is possible to identify the main mechanisms brought into play in material removal leading to paint stripping. The chemical strippers used are methylene chloride, phenolic compounds, and activated acids or activated bases free from phenols, chromates or methylene chloride. However, the methylene chloride and phenolic compounds are being replaced by a new generation of chemical strippers which are less active and their solvent power is lower. To improve the chemical kinetics, 'active' elements are introduced into the composition of these products. Mechanical stripping includes technologies using mechanical phenomena based on erosion, achieved by friction or blasting particles. Thermal stripping, the last classification, makes use of electronics and automation.

BACKGROUND TO PLASTIC MEDIA BLASTING

Foster, Terry, Esquimalt Defence Research Detachment, Canada; AGARD, Environmentally Safe and Effective Processes for Paint Removal; Apr 1, 1995, 3 p; In English; See also 19950025744; Copyright; Avail: CASI; A01, Hardcopy; A01, Microfiche

Chemical strippers based on active phenolic components in a chlorinated solvent have been the traditional method for removing of paints and coatings from aircraft. With the recent recognition of the environmental and health concerns of chlorinated solvents and the problem disposing of phenols there have been some major developments in paint removal technology. One of the first techniques developed to replace chemical strippers and now one of the most widely used techniques for paint removal from aircraft was plastic media blasting (PMB). The PMB technique is similar to traditional grit blasting (slag, sand alumina or carborundum) techniques used on steel and other metals (based on grits) but using polymer based media that are softer and less aggressive. Plastic media are ranked by hardness and density as well as chemical composition.

DRY MEDIA BLASTING WITH WHEAT STARCH

Foster, Terry, Esquimalt Defence Research Detachment, Canada; AGARD, Environmentally Safe and Effective Processes for Paint Removal; Apr 1, 1995, 11 p; In English; See also 19950025744; Copyright; Avail: CASI; A03, Hardcopy; A01, Microfiche

The brand name TECHNOSTRIP covers several types of installations and facilities. These were developed mainly to meet the requirements of customers in the aeronautic field. The range of products includes: complete self-supporting and semi-automated system for aircraft stripping; large-size blasting booth for semi-automatic stripping; manual blasting booth; and sealed and portable manual stripping head. Wheat starch media was developed for particle blasting stripping and is used in TECHNOSTRIP. This paper reviews its origins and use as well as use of automated facilities, reliability, effects on materials, effects on environment, and utilization examples.

Water blasting is a paint removal technique that has been used for cleaning and paint removal for many years. The major disadvantages until recently were the slow rate of paint removal and the possibility of damage to the substrate from the high pressures used. With the improvement in nozzle design that allows for higher operating

pressures and the use of environmentally compliant paint softeners or strippers, water blasting is becoming a recognized technique for paint removal in the aircraft industry.

PAINT REMOVAL AND SURFACE CLEANING USING ICE PARTICLES

Foster, Terry, Esquimalt Defence Research Detachment, Canada; Visaisouk, S., Ice Blast International Corp., Canada; AGARD, Environmentally Safe and Effective Processes for Paint Removal; Apr 1, 1995, 9 p; In English; See also 19950025744; Copyright; Avail: CASI; A02, Hardcopy; A01, Microfiche

Research into the possibility of using ice particles as a blast medium was first initiated at Defence Research Establishment Pacific (DREP) in an effort to develop a more environmentally acceptable paint removal method. A paint removal process was also required that could be used in areas where normal grit blasting could not be used due to the possibility of the residual blasting grit contaminating machinery and other equipment. As a result of this research a commercial ice blasting system was developed by RETECH. This system is now being used to remove paint from substrates that cannot be easily blasted by conventional techniques and also to clean soiled or contaminated surfaces. The problems involved in the development of an ice blast system and its components and their functions are described. Due to the complexity of paint removal using ice blasting, parameters such as air pressure, ice particle size and ice particle flow rate were studied and adjusted to suit the nature of the particular coating and substrate of interest. The mechanism of paint removal by ice particles has also been investigated. A theoretical model has been developed to explain the different paint removal mechanisms such as erosion by abrasion and erosion by fracture as they relate to ice blasting. Finally, the use of ice blasting to remove paint from a variety of substrates is presented as well as examples of surface cleaning and surface decontamination.

Mechanical-type stripping using dry ice (solid CO₂) consists in blasting particles of dry ice onto the painted surface. This surface can be used alone or in duplex according to type of substrate to be treated. According to operating conditions, three physical mechanisms may be involved when blasting dry ice particles onto a paint system: thermal shock, differential thermal contraction, and mechanical shock. The blast nozzle, nozzle travel speed, blast angle, stripping distance, and compressed air pressure and media flow rate influence the stripping quality and the uniformity and efficiency obtained.

The Aquastrip stripping process is a mechanical process. It consists of applying a high-pressure water jet by means of a rotating stripping head with two water jets. The efficiency of these water jets is improved in certain cases by using a paint softener before applying the water jet process.

At the end of the 80's, some of the large European airlines expressed a wish for paint systems with improved strippability on their aircraft, allowing the possibility to strip down to the primer without altering it, using 'mild' chemical strippers based on methylene chloride. These improvements were initially intended to reduce costs and stripping cycle times while facilitating rapid repainting, and this without the need to change the conventionally used industrial facilities. The level of in-service performance of these paint systems was to be the same as the previous ones. Requirements related to hygiene safety and the environment were added to these initial requirements. To meet customers' expectations, Aerospatiale, within the Airbus Industry GIE, formed a work group. This group was given the task of specifying, following up the elaboration and qualifying the paint systems allowing requirements to be met, in relation with the paint suppliers and the airlines. The analysis made in this report showed the interest of transferring as far upstream as possible (to paint conception level) most of the technical constraints related to stripping. Thus, the concept retained for the paint system, allowing selective chemical stripping, is a 3-coat system with characteristics as near as possible to the previously used paints.

OPERATIONAL PARAMETERS AND MATERIAL EFFECTS

Foster, Terry, Esquimalt Defence Research Detachment, Canada; AGARD, Environmentally Safe and Effective Processes for Paint Removal; Apr 1, 1995, 6 p; In English; See also 19950025744; Copyright; Avail: CASI; A02, Hardcopy; A01, Microfiche

Although there are six types of plastic media, the focus on operational parameters and materials effects of PMB (plastic media blasting) will be on the Type 5 acrylic media with some reference and comparisons to Type 2 media. The other four plastic media are not used extensively in general aircraft stripping and will not be discussed in this paper. There are several military and commercial documents available with detailed procedures for plastic media stripping of aircraft. The actual choice of blasting parameters will, to a great extent, depend on the media chosen and the substrate to be stripped. The effects of various blasting conditions on materials can be evaluated using visual, optical microscopy, scanning electron microscopy (SEM) and mechanical and corrosion test methods. In some test methods up to twelve specimens are required to give meaningful results, therefore statistical analysis tools are also required to interpret the results due to the scatter in some of the data.

It is not always easy to conduct a study and implement a systematic policy in the aeronautical paint stripping field. The situations to be studied are complicated by extensive technical data, material conditions and financial unknowns. To these are added demands both in the civil and military fields to increase the performance obtained, optimize cycles, reduce recurrent costs, quickly amortize investments and now increasing respect for the environment. To reply correctly, the various possibilities must be assessed using, if possible, identical criteria and reference systems. The only criterion which applies to all the processes and methods is the overall stripping cost. It is not sufficient for a process to meet the related technical requirements (for example 'IATA guidelines'), it must also be economically justifiable. The overall costs take into account therefore the costs and materials, labor and also the downtime of the aircraft, amortization and maintenance of the

31 ENGINEERING (GENERAL)

installations and processing of waste, etc. For many years now, AEROSPATIALE has undertaken research and development programs to find and evaluate alternatives to the conventional chemical stripping process. This work has led it to carry out comparative analyses from technical elements enhanced as the work progressed. Derived from text

For several years now, the main civil aircraft manufacturers (Airbus and its partners, Boeing, Fokker, McDonnell Douglas) have been working jointly on the writing of technical recommendations and the drawing up of an international standard. This work concerns the evaluation of the processes and products used to strip aeronautical paint systems. This procedure was initiated on request from the main airlines. In effect, the airlines are faced with situations in which the financial and operational objectives are becoming increasingly important. The need was felt to rationalize and, if possible, harmonize the criteria and technical requirements of the various civil aircraft manufacturers in order to facilitate in-service maintenance of the fleets of airlines operating Airbus, Boeing, Douglas aircraft, etc.

G., Virginia Univ., USA; Smart Structures and Materials: Implications for Military Aircraft of New Generation; Oct. 1996; 24p; In English; 41st; Sagamore Conference, USA; Sponsored by Department of the Army, USA; See also 19970001697; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Intelligent Processing of Materials (IPM) is an emerging methodology for simulating and controlling the processing and manufacture of materials. It is finding widespread application during the manufacture of electronic, photonic and composite (i.e. high performance) materials, primary metals such as steel/aluminum and is an enabling technology for smart materials/structures synthesis/processing. IPM simulation tools seek to create, at the level of an engineering workstation, a 'virtual' version of a process. They combine process models for a material's response to processing stimuli (e.g. pressure, temperature, environmental conditions, etc.) with characteristics of the process equipment to predict the material's performance defining attributes at the completion of the process. IPM controllers are an innovative extension of today's state-of-the-art in control technology. They exploit the recent availability of noninvasive sensors that sense critical product variables during the process. This new knowledge about the state of the process, together with the process models, can be used

to plan and execute feedback control schemes leading to smart materials with 'goal state' combinations of performance defining property attributes.

The following aspects of cryogenic engineering and basic properties of materials are considered: (1) The oxygen-nitrogen binary phase diagram and the formation of liquid oxygen in unsealed insulation systems. (2) The large liquid/gas volume expansion and the dangers inherent in the pressure created in closed containers. (3) Nucleate and film boiling in liquid nitrogen, the different heat transfer rates in between solid/liquid and solid/gas, operation of liquid nitrogen level sensors and of electric immersion heaters used to evaporate liquid nitrogen. (4) Safe working practices for handling liquid nitrogen, the physiological effects of oxygen deficiency, anoxia and asphyxiation, the use of oxygen monitors, breathing apparatus, condensation clouds and nitrogen concentration, escape routes and victim rescue. (5) The cause and avoidance of cold burns by good working practice and the use of protective clothing. (6) Storage of liquid nitrogen and its transfer using bare and insulated transfer lines over long and short distances. (7) Selection of materials for their LOX compatibility and for the avoidance of moisture desorption. (8) Thermal contraction of metals and non-metals, problems caused by temperature gradients and the use of materials with mis-matched expansion coefficients. (9) Thermal conductivity and insulation, heat capacity, thermal response times and thermal shock.

The objective of this AGARD Specialists' Meeting on Bolted/Bonded Joints in Polymeric Composites was to examine the state of the art in joining polymeric composites, to consider the relative merits of the various methods and to highlight gaps in the technology which should be addressed. The papers presented cover a number of aspects concerning the application of adhesively bonded and mechanically fastened joints in the analysis, design, manufacturing, and repair of fiber-polymer composites. The focus is on aerospace rather than commercial products.

In recent years, a great deal of important materials and process R&D has resulted in new or modified aerospace materials that are more environmentally benign. These new materials are implemented on a limited basis, however, wide spectrum materials substitutions are rare because many of the new materials have characteristics that may not fully meet traditional performance standards. Also, as is the case with the phosphoric sulfuric acid anodize process as a substitute for the chromic acid anodize, some processes are less controllable or robust and therefore may suffer when production scale-up of laboratory developed technology is attempted. While low volatile organic compounds (VOC), water-reduced and non-chromate inhibited organic coating technology is developed and being optimized, inorganic finishing and electroplating technology is still immature and many different technologies are under evaluation. Widely implementable materials and process substitutes for electroplated cadmium and chromium are not currently available and therefore require continued investment in research and development.

Environmental laws, regulations and policies require that traditional cleaners (1,1,1 trichloroethane, Methyl Ethyl Ketone and CFC113) be eliminated from current and future cleaning operations. In order to achieve this goal the Air Force has determined that pollution prevention is the preferred approach. Aqueous cleaning has been the predominant replacement cleaning technology to reduce or eliminate hazardous cleaning waste. However, this tends to shift the waste stream from air to water. The USA Air Force, Wright Laboratory decided to investigate minimal waste cleaning technologies for pre-bonding and precision cleaning processes. Four technologies are being developed to meet the needs of DOD depots, namely, Supercritical CO₂ Convection Flow cleaning, Low-Temperature Oxygen Plasma cleaning, Laser Cleaning and CO₂/UV light cleaning. Each of these technologies produces no more waste than the contaminant they are removing. Supercritical CO₂ Convection Flow cleaning is much simpler and more flexible than traditional supercritical CO₂ cleaning processes, avoiding high pressure pumps which tend to increase cost, complexity and cycle-time. Low-temperature oxygen plasma cleaning breaks down hydrocarbon contamination in oxygen tubing resulting in benign cleaning residue which is entrained in the vacuum flow and removed from the tube. Laser cleaning utilizes laser energy to remove tightly bound contaminants and coatings. The CO₂/UV light cleaning system has demonstrated its cleaning effectiveness for a large number of shop soils. Surfaces cleaned with this method exhibit excellent bondability.

Chromic Acid Anodizing (CAA) is often applied in the European aircraft industry for pretreatment of aluminum substrates before coating for corrosion protection and before structural adhesive bonding. By this usage, the quality requirements for any alternative process is set with respect to adhesion performance, corrosion protection and fatigue properties, including the compatibility to proven processes and materials. At DASA, the Phosphoric Sulfuric Acid

Anodizing process (PSA) was elaborated and verified from laboratory scale up to industrial shop trials. Results reaching from characterizing the oxide morphology by electron microscopy to quality assurance tests on full scale parts are presented.

EVALUATION OF AQUEOUS DEGREASING AS REPLACEMENT FOR VAPOUR DEGREASING WITH 1,1,1-TRICHLOROETHANE AT BOMBARDIER-CANADAIR

Alcorta, Hector, Bombardier, Inc., Canada; Menard, Daniel, Bombardier, Inc., Canada; Lizee, R., Bombardier, Inc., Canada; Environmentally Compliant Surface Treatments of Materials for Aerospace Applications; Feb. 1997; 10p; In English; See also 19970023078; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

Back in 1990, in view of the environmental regulations in the U.S., and supporting Canada's commitment to the Montreal Protocol, Bombardier-Canadair started investigating the feasibility of using aqueous degreasing to replace vapor degreasing with 1,1,1-trichloroethane (TCA). This paper presents the results of Canadair's laboratory-scale and pilot line evaluations. Because of the large variety of parts sizes and shapes produced at Canadair, it was decided to evaluate aqueous degreasing by immersion with mechanical agitation or solution recirculation. Seven candidate aqueous degreasers were selected for evaluation based on data obtained from several airframe and aircraft manufacturers who had already evaluated many products. The twelve contaminants most commonly found on parts going through the vapor degreasers at the time of the study were identified and used for the evaluation. Both TCA and an alkaline cleaner already in use at Canadair were used as controls. From the seven aqueous degreasers evaluated, only three met all the criteria. Laboratory results indicated that, when used as specified, these three degreasers did an acceptable job of removing the contaminants. Therefore, these cleaners were considered acceptable to be used in an immersion process at Canadair as substitutes for vapor degreasing with TCA, and were recommended for pilot line evaluation. One of the three candidates was tested in a pilot line and then successfully implemented into production.

A Garteur (Group for Aeronautical Research and Technology in Europe) collaborative program of research being undertaken to evaluate alternatives to cadmium plating for the corrosion protection of high strength steel aerospace components and fasteners is described. Coatings being investigated include electrodeposited zinc-nickel and zinc cobalt-iron, ion vapor deposited and electrodeposited aluminum,

31 ENGINEERING (GENERAL)

metallic-ceramic deposits containing zinc and aluminum flakes and magnetron sputtered aluminum magnesium coatings. The program is examining both the corrosion resistance of the coatings and their galvanic compatibility with aluminum alloy airframe materials. The effects of coatings on fatigue life and susceptibility to hydrogen embrittlement are being determined. Physical properties including conductivity and lubricity are being studied, microstructure and resistance to aircraft fluids. The program involves research in seven laboratories from the aerospace research institutes and the aircraft industry based in France, Germany, The Netherlands, Sweden and the United Kingdom.

R&D TO DEVELOP SUBSTITUTES FOR ELECTROPLATED HARD CHROME

Reinhart, Theodore J., Wright Lab., USA; Feb. 1997; 5p; In English; See also 19970023078; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

Hexavalent chromium (CR(+6)) is the ionic species used in the traditional electroplating of chromium for corrosion and wear resistance, referred to as electrolytic hard chromium (EHC). The resulting coating provides not only a hard wear resistive barrier, but also has lubricity making it ideal for hydraulic applications. Typical applications include landing gear components, flight control actuators, gun barrels, and turbine engine components. EHC plating is used for both rebuilding worn parts and as a protective coating by original equipment manufacturers. The U.S. Environmental Protection Agency (EPA) has determined hexavalent chromium to be detrimental to health and the environment. Hexavalent chrome is known carcinogen, with some studies indicating a fifteen fold increase in instances of lung cancer among workers exposed to chrome plating operations. This substance is on the EPA list of 17 toxic compounds and is in the 33/55 program for reduction of hazardous materials. In January 1995, the EPA released new Clean Air Act rules to limit emissions from EHC operations. As a result, the Occupational Safety and Health Administration (OSHA) is proposing to decrease the exposure limit from .1 mg/m(exp 3) to .005 mg/m(exp 3). Reducing emissions to this new level will greatly increase the operating cost of EHC plating. This has led to investigation of several alternative coatings and coating processes.

The use of cadmium and chromium as electroplating metals continues to come under criticism from several directions. Both materials have been targeted by the USEPA for reduction/elimination. The toxicity of specific forms of both metals is widely known and efforts are underway to identify workable alternatives for both materials. This paper presents the methodology and results of tests performed to identify performance properties of select cadmium and chromium substitutes. These results and their interpretation are not to be inferred to be official US Navy policy.

This paper describes two emerging munition technologies beneficial to Unmanned Tactical Aircraft (UTA) and attempts to define a necessary weapon load capability. to determine a weapon/loadout combination that maximized the lethal effectiveness of an UTA while minimizing the payload weight required, a mission level analysis was conducted and concludes that a minimum of 1000-lb (454 kg) of payload provides an UTA a viable air-to-ground combat mission capability. A 2000-lb (908 kg) payload provides an increased effectiveness but must be contrasted with the associated increase in UTA cost, size, weight and propulsion needed to employ the additional payload weight.

Several specific technologies relating to design approaches, design concepts, and manufacturing processes are being developed now that will lead to more integrated structure for future airframes. Unitized aircraft structures will be combinations of advanced composite and metallic structures that allow for designs with reduced numbers of fabricated parts and assembly steps. Material selection will be made on the basis of load condition and intensity, temperature range, specific strength, specific cost, or critical factors based on structural application. Low cost manufacturing will be influenced primarily by design, with no single material system or manufacturing process being the preferred path. Design concepts that emphasize more unitized structure are synergistic with manufacturing processes that emphasize fabrication of articles that are virtually the finished

product. Systems integration issues are major players to achieving low cost manufacturing, and new approaches to design and manufacturing of these subsystems are critical.

TMD DETECTION AND TRACKING USING IMPROVED AWACS SENSORS

Petersen, Steve, Ballistic Missile Defense Organization, USA; Kinashi, Yasuhiro, Nichols Research Corp., USA; Leslie, Daniel, Schafer, W. J. Associates, Inc., USA; AGARD, Guidance and Control for Future Air-Defence Systems; Jan 1, 1995, 10 p; In English; See also 19950025702; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper identifies an UOES (User Operational Evaluation Systems) version of an airborne surveillance sensor funded by the BMDO (Ballistic Missile Defense Organization). The sensors will be integrated into an operational AWACS E-3 upgrade program. This BMDO program initiative is called Extended Airborne Global Launch Evaluator, or EAGLE. Initial Operational Capability (IOC) of the EAGLE system will be ready in time to support the THAAD/GBR UOES capability. This airborne system, when developed, will consist of a passive infrared surveillance sensor (IRSS) with an active laser-ranger, on board an upgraded AWACS E3 aircraft to operate effectively in the TMD (theater missile defense) mission. The objective for the EAGLE is to field, in a reasonably short time and at a relatively low cost, a cueing sensor capability in regional conflicts to augment the existing space-based surveillance systems. With autonomous surveillance capability to search a wide-sector field, the EAGLE can detect and track boosting TBM's shortly after launch or as they break the clouds. Its passive IR sensor can also detect and track warm hardbody targets. Together with its laser-ranger, it is able to determine, immediately after the booster burn-out, very precise target state vectors that are accurate enough to predict their eventual impact points, to cue fire control radars, and to engage the weapons, if needed. Its primary TMD mission is to provide precise cueing of fire control radars to initiate the active defense weapon systems. Accurate cues from the EAGLE will off load radar resources to enable earlier detection of the targets at longer extended ranges, thereby increasing the interceptor battlespace for potentially more effective defense engagements and opportunities. It can also provide a precise early warning message to enable immediate TBM attack assessment and appropriate selection of defense engagement options by the battle manager. The functions of the sensor suite can be distributed, such that it can be tasked independently to observe the threat intercept, while providing continuous surveillance of new TBM launches, to support the kill assessment function for shoot-look-shoot opportunities. Another potential function that can be performed by the EAGLE is the estimation of TMD launch points (LPE) for counterforce support. This technical paper provides an expanded discussion of the EAGLE's mission roles, specific system functions, and its detection and tracking performance capability. The paper also addresses the sensor and the laser subsystem design characteristics and operational modes required to accomplish all its functions. Initial analyses indicate that the impact of scattering and absorption of the IR signatures and laser signals will be minimal on the performance of the system. Recent satellite data provides measurement of atmospheric extinction. Propagation statistics, based on satellite observations are presented for global regions of interest to TMD.

MULTISENSOR DATA FUSION FOR INTEGRATED MARITIME SURVEILLANCE

Premji, A., Raytheon Canada Ltd., Canada; Ponsford, A. M., Raytheon Canada Ltd., Canada; AGARD, Guidance and Control for Future Air-Defence Systems; Jan 1, 1995, 12 p; In English; See also 19950025702; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

A prototype Integrated Coastal Surveillance system has been developed on Canada's East Coast to provide effective surveillance out to and beyond the 200 nautical mile Exclusive Economic Zone. The system has been designed to protect Canada's natural resources, and to monitor and control the coastline for smuggling, drug trafficking, and similar illegal activity. This paper describes the Multiple Sensor - Multiple Target data fusion system that has been developed. The fusion processor has been developed around the celebrated Multiple Hypothesis Tracking algorithm which accommodates multiple targets, new targets, false alarms, and missed detections. This processor performs four major functions: plot-to-track association to form individual radar tracks; fusion of radar tracks with secondary sensor reports; track identification and tagging using secondary reports; and track level fusion to form common tracks. Radar data from coherent and non-coherent radars has been used to evaluate the performance of the processor. This paper presents preliminary results.

MULTIPLE TARGET TRACKING BASED ON CONSTELLATION MATCHING AND KALMAN FILTER

Wong, Andrew K. C., Waterloo Univ. Ontario, Canada; Leung, Henry, Defence Research Establishment Ottawa, Canada; AGARD, Guidance and Control for Future Air-Defence Systems; Jan 1, 1995, 22 p; In English; See also 19950025702; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

A new approach to multiple target tracking (MTT) problem is developed. The data association (DA) problem is solved by an attributed subgraph isomorphism approach called constellation matching (CM). The CM method exploits, in the most direct way, the spatial configuration of the collection of targets which are subject to temporal and spatial constraints. The CM-based tracking system combines the CM technique with the Kalman filter to track and confirm the trajectories of multiple targets. The efficiency of this new approach is demonstrated using real-life multiple target radar tracking data and the results are compared to those obtained by a multiple hypothesis tracking (MHT) system.

Air forces across the world strive to protect their valuable resources from both the air and ground threats. Over the past few years, the surface-to-air missile threat has become more sophisticated and more deadly. It is far cheaper and less technical for a country to own and operate a ground missile system than to maintain a credible air force. It is for this reason that the attention to the ground threat has grown over the past few years. This paper discusses the approach the U.S. Air Force has taken in protecting its aircraft from these ground

threats and how the mission of Lethal Defense Suppression has evolved into the complimentary tasks of Reactive Suppression and Pre-emptive Destruction.

USING A RED TEAM TO DEVISE COUNTERMEASURES

Swedenburg, R. L., Ballistic Missile Defense Organization, USA; AGARD, Guidance and Control for Future Air-Defense Systems; Jan 1, 1995, 12 p; In English; See also 19950025702; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The ability of a defense system to operate effectively when deployed in battle is dependent on designs able to deal with countermeasures against the defense. The formation of a technical Red Team to stress the preliminary designs of the defensive system with technologically feasible and effective potential countermeasures provides a means to identify such potential countermeasures. This paper describes the experience of the U.S. Ballistic Missile Defense Organization's (BMDO) Theater Missile Defense Red Team since the Gulf War in 1991, the Red-Blue Exchange process, and the value it has provided to the designers of the U.S. Theater Missile Defense systems for developing robust systems. A wide-range of technologically feasible countermeasures has been devised, analyzed, tested for feasibility, and provided to the system developers for mitigation design. The process for independently analyzing possible susceptibilities of preliminary designs and exploiting the susceptibilities to identify possible countermeasures is explained. Designing and characterizing the Red Team's countermeasures, determining their feasibility, and analyzing their potential effectiveness against the defense are explained. A technique for the Blue Team's designers to deal with a wide range of potential countermeasures is explained.

HELICOPTER HF COMMUNICATIONS USING THE NVIS MODE

Proia, M., Elmer, Italy; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 12 p; In English; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The importance of helicopters in the battlefield scenarios is significantly increasing as the new weaponry and guidance control systems allow use of helicopters in a multiplicity of roles, ranging from anti-tank operations to rapid transportation of men and materials. Missions are often assigned to the helicopters that require flying at close distance from the enemy positions. In these cases, low-altitude flying is necessary for survivability and this type of operation, designated as Nap-Of-Earth (NOE) flying, is a well established helicopter tactic for concealment against enemy fire. In the ordinary modes of operation, radio communications between the helicopter and other platforms in the tactical area are supported by the VHF1 (30 to 88 MHz), VHF2 (108 to 172 MHz), and UHF (225 to 400 MHz) frequency bands over line-of-sight (LOS) links. The VHF1 band is used by the helicopter to communicate with ground forces during RECCE missions and to interact with other battlefield units for mission management and briefing. The VHF2 band is dedicated to communications with the Base for ATC purposes, while the UHF band is universally used for Ground-Air-Ground and Air-to-Air links in Air Defense operations. As NOE altitudes for helicopters are typically in the order of a few feet, LOS conditions are seldom achieved due to interposed obstacles (such as vegetation or a hilly landscape) or simply because at NOE altitudes the distance between the communicators may well exceed the LOS range. In this scenario precluding effective use of tactical VHF, helicopter to ground and helicopter to helicopter links can be reliably established over battlefield distances by use of the HF propagation mode known as Near-Vertical - Incidence-Skywave (NVIS), whereby an RF signal with a high angle of incidence

(greater than 80 degrees) is reflected by the ionosphere back to earth producing an umbrella-type coverage. By appropriate selection of the operating frequency in 1 to 2 MHz passbands (windows) located in the 2 to 10 MHz range, NVIS provides gapless coverage over distances up to 300 km.

THE ANGLO-FRENCH COMPACT LASER RADAR DEMONSTRATOR PROGRAMME

Hogg, G. M., Defence Research Agency, UK; Harrison, K., Defence Research Agency, UK; Minisclou, S., STTE, France; AGARD, Low-Level and Nap-of-the-Earth (NOE) Night Operations; Jan 1, 1995, 8 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

CLARA is an Anglo-French Compact Laser Radar technical demonstrator program. It is a multi-mode CO₂ laser radar, the primary mode being cable and obstacle warning, with additional modes including terrain following and a range of targeting modes. The 3 1/2 year program will provide both France and the UK with a podded equipment in 1996. The UK will carry out fixed wing trials and France will fit their pod on a helicopter. The flight trials data are being exchanged between the two countries.

HELIRADAR: A ROTATING ANTENNA SYNTHETIC APERTURE RADAR FOR HELICOPTER ALLWEATHER OPERATIONS

Kreitmaier-Steck, W., Eurocopter Deutschland G.m.b.H., Germany; Wolfram, A. P., Deutsche Aerospace A.G., Germany; AGARD, Dual Usage in Military and Commercial Technology in Guidance and Control; Mar 1, 1995, 8 p; In English; See also 19950026705; Copyright; Avail: CASI; A02, Hardcopy; A02, Microfiche

Today, available radar instruments cannot be applied for flight guidance purposes due to lack of resolution and ground elevation information. On the other side, optical sensors such as infrared systems provide an excellent resolution but are nearly blind at adverse weather conditions such as fog and rain. A new radar technology called ROSAR (Synthetic Aperture Radar based on ROTating antennas) promises to overcome the deficiencies of the traditional radar systems. On the basis of encouraging research work on ROSAR-technology and an investigation of the feasibility of a piloting system based on these ideas, Eurocopter Deutschland and Deutsche Aerospace started a development program called HeliRadAR to develop a ROSAR-based piloting system. This device should be able to provide photolike images even under extreme visibility conditions. Details on the investigation and the resulting concepts for synthetic vision based flight guidance at Eurocopter will be given. Following an

introduction to the basics of ROSAR-technology, the technical concept of HeliRadar will be presented. The paper concludes with a discussion of the perspectives for civil and military applications.

TRANSIENT ANTENNA DESIGN PARAMETERS FOR OPTIMIZING RADIATED PULSE

Lambert, A. P., Defence Research Establishment Ottawa, Canada; Booker, S. M., Defence Research Establishment Ottawa, Canada; Smith, P. D., Defence Research Establishment Ottawa, Canada; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 12 p; In English; Sponsored by the Defence Research Agency, UK; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Antenna structures capable of supporting (essentially) transverse electromagnetic (TEM) spherical wave are characterized by their frequency independence over a wide band width, making them ideal candidates for transient field generation and reception. In particular, the triangular plate configuration of the TEM horn is of interest for a variety of directive wide band applications, including nuclear EMP simulation, impulsive field detection, ultra-wide-band radar pulse transmission, and feeds for paraboloidal reflector antenna systems. The basic design for such structures is based on that of idealized, infinitely long, conical antennas. However, in producing practical antennas, which optimize the required characteristics of the radiated pulse train, several modifications to the original design are possible. This paper will discuss two particular features of the TEM horn design: the prediction of the characteristic impedance for a given structure and the effect of the horn profile on the output pulse.

This paper concerns the use of time- and frequency-domain methods for computing the interaction of high power microwaves with simple and complex structures. Effects of various factors - the geometric modelling of the structure, the Fourier transformation, the

shape of the incident pulse, etc. - on the CPU-time and the accuracy of the solution are demonstrated. Results of our computations for various structures are presented.

A PROCEDURE BASED ON LINE THEORY FOR CALCULATING SURFACE CURRENTS AND COUPLING INTO THE INTERIOR OF LARGE OBJECTS

Arnold, E., Deutsche Aerospace A.G., Germany; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 10 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

For objects which are too large to be calculated with the MM or the FDTD an approximation based on line theory was developed. For calculating an object a wire grid model is made. This model is described by Z-Matrix coefficients which are calculated approximately using line theory. The coupling of the wires are taken into account. Having the Z-matrix takes less effort to determine the currents at some special points of the object. Though the procedure is designed for the calculation of big objects compared to a wavelength, some results for simple objects are shown and compared with the results received by different methods.

FREQUENCY-DOMAIN ANALYSIS ON NONLINEARLY LOADED THIN-WIRE ANTENNAS AND NETWORKS

Noujeim, Karam M., Toronto Univ. Ontario, Canada; Zaky, Safwat G., Toronto Univ. Ontario, Canada; Balmain, Keith G., Toronto Univ. Ontario, Canada; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 5 p; In English; Copyright; Avail: CASI; A01, Hardcopy; A03, Microfiche

Electronic devices are susceptible to a wide variety of high-level electromagnetic interference signals, from medium to microwave frequencies. The ability to assess the susceptibility of these devices to interference using computational techniques is an important asset to the designer. An essential ingredient in this process is the ability to combine linear field computations with nonlinear circuit analysis. A frequency-domain based computer program, known as TWIRE, has been developed for the periodic steady-state analysis of thin-wire antennas and scatterers loaded with nonlinear circuits. In addition to linear and nonlinear resistors, capacitors, and inductors, these circuits may contain transformers, diodes, transistors, N-port networks, etc. The computer program is based on an S-parameter technique that combines the thin-wire of moments with a frequency-domain-based nonlinear circuit simulator employing harmonic balance. The program is applicable to arbitrary-size wire networks and antenna structures loaded with circuits such as amplifiers, attenuators, detectors, filters, multipliers, and mixers. The program has been tested on various nonlinearly loaded antennas structures. Its predictions are found to be in agreement with measured results, and with analytical results published in the literature.

HPM COUPLING TO A CYLINDRICAL TARGET WITH SELECTED BUILT-IN COMPONENTS

Magg, M., Industrieranlagen-Betriebsgesellschaft m.b.H., Germany; Nitsch, J. B., NBC Defense Research and Development Inst., Germany; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 10 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

A numerical simulation of HPM coupling to small missiles is described. The main interest is the current induced on the interior cabling in the resonance region. The results of the numerical solution

agree very well with real measurements performed on a test model. For a more realistic missile design we will find a very big reduction of the HPM coupling into the missile if its metallic fin system is replaced by a non-conducting one. Finally, we comment on the relation between maximum possible response and the shape of the incident microwave pulse.

This paper describes our low power microwave coupling measurements on terminally guided missiles in the frequency range between 100 and 8000 MHz. The plane wave excitation experiments have been carried out in our field coupling facility, which consists of an asymmetric triplate transmission line with maximum field levels of about 40 V/m in the working volume. As test objects we examined five (semi) autonomous guided missiles. Three of them, former experimental studies from the Diehl company (GE), are presented in this paper. The test objects were positioned in the simulator in three orthogonal orientation with respect to the external field and were not connected to a power supply (inactive condition). In order to be able to systematically analyze the interaction of the external electromagnetic fields with the avionics and its wiring, we had to divide the investigations into three independent phases, namely, external interaction with the fuselage, mode of penetration to the interior of the missile and excitation of the electrical systems and the cabling. The coupling paths depend very much on the design principles of the airframe. The main threat identified was back door coupling via those wings and fins, which are not attached galvanically to the outer surface of the hull. Because of flight guidance, these parts are fastened through slots to the bearings of the motor drives inside the missile. The dominant cable resonances sometimes can be traced back to the resonances of the wings and/or fins and the type of cabling. Another threat was coupling via the long slots required for the folding wings. These shafts penetrate the whole body and enable the external fields to couple into the interior. The peak amplitudes at the ends of the cables were found to be between 50 to 500 (micro A/(V/m)), depending on the test object.

The battle field of the present and even more the one in future will be characterized by the use of weapon systems with a high degree of electronics, computers, and sensors, designed and built to keep not only the man out of the loop. But the higher the technology used for smart weapon systems, the more these systems are endangered by numerous sources of hazard. One of those sources is the threat caused by induced or natural electromagnetic fields. These threat factors can be generated by natural, civil and military environment. In principle there are two main applications which must be considered in military applications: Firstly, weapon systems, that is, high power microwave sources as well as intelligent electromagnetic radiation systems to defeat ammunition on the battle field and secondly, the hardening of the own smart ammunition systems and missiles against the interference sources created by the different types of electromagnetic fields. This report will discuss the possible electromagnetic

coupling effects on smart ammunition and missiles and their typical interference caused on the electronics and sensor level. Real time 6-DOF simulations show the flight mission which may be compromised depending on the coupled electromagnetic fields. The German MOD has established a research program where smart ammunitions with different seeker systems are investigated in respect of the coupling effects on smart ammunition caused by high power microwaves. This program considers all available resources and know how in Germany. The systems are investigated by analytical, numerical, and experimental methods with passive and activated missiles.

CALCULATION AND MEASUREMENT OF HPM FIELDS SCATTERED BY A TARGET WITH OPENINGS

Kashyap, S., Defence Research Establishment Ottawa, Canada; Burton, M., Defence Research Establishment Ottawa, Canada; Louie, A., Defence Research Establishment Ottawa, Canada; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 6 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper concerns the computation and measurement of HPM (High Power Microwaves) fields inside and outside a structure with openings. RCS computations and measurements are made for a number of targets. The computations use both frequency-domain and time-domain methods, and the results are then compared with those measured in an anechoic chamber. An attempt is made to correlate various quantities such as the RCS, the scattered fields inside a structure, and the time-domain scattered far-fields. It is shown that some of the scattered far-field quantities may be used to identify the target scattering centers, the frequencies at which maximum coupling occurs, and the cut-off frequencies of a target.

This paper presents a method for coupling analysis allowing to determine the worst case of stress (frequency, polarization and attitude angles) of a target by an electromagnetic wave. The approach is based on the determination of the radiated pattern of the device under test, considered as a transmitting antenna, using near field measurements. The coupling can be determined using the reciprocity theorem.

INVESTIGATION OF RF COUPLING WITH UWB RADAR

Taylor, A. J. E., Defence Research Agency, UK; Clement, R. A., Defence Research Agency, UK; Hall, C., Defence Research Agency, UK; Parkes, D. M., Defence Research Agency, UK; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 4 p; In English; Copyright; Avail: CASI; A01, Hardcopy; A03, Microfiche

Direct experimental investigations of the coupling of microwave to military systems involves technically difficult instrumentation of the equipment. The problems associated with instrumenting the equipment can be avoided by exploiting the properties of ultrawideband radar. Illumination of a target by a short duration, fast risetime electromagnetic pulse results in a back scattered response which is formed by a combination of the early reflections of the incident pulse, and later natural resonances of the object. We compare experimental and

computational studies of the responses of a generic missile seeker head in order to assess what impulse radar reveals about coupling to a target.

ELECTROMAGNETIC SHIELDING PROPERTIES OF COMPOSITE MATERIALS

Gardner, C. L., Defence Research Establishment Ottawa, Canada; Apps, R., Defence Research Establishment Ottawa, Canada; Russell, A. J., Defence Research Establishment Pacific, Canada; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 12 p; In English; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

In order to ensure that composite structures have adequate electromagnetic (EM) shielding, a knowledge of the EM properties of anisotropic laminated materials is necessary. In this paper, we provide an overview of work we have carried out to measure the intrinsic EM shielding properties of carbon and non-carbon epoxy laminates. These experimental results are compared with numerical results that have been calculated using the Method of Moments. Finally, results showing the effect of repair of carbon/epoxy composites on shielding properties are presented.

HARDENING AGAINST A COMBINED ELECTROMAGNETIC THREAT

Dion, M., Defence Research Establishment Ottawa, Canada; Gardner, C., Defence Research Establishment Ottawa, Canada; Kashyap, S., Defence Research Establishment Ottawa, Canada; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 10 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Hardening against the electromagnetic environment is usually done by considering each threat separately. In recent years, there has been an increasing interest in methods for unifying electromagnetic standards and procedures to simplify the design and testing of hardening techniques. This approach is appealing as it could reduce the cost of system design as well as the cost of testing. The objective of this paper is twofold: firstly, to assess the feasibility of combining the various electromagnetic threats to simplify the design of electromagnetic protection; and secondly, to assess the feasibility of using a single test, or at least a minimum number of tests, to verify the electromagnetic hardness of a system.

MODELING AND NUMERICAL SIMULATION OF MICROWAVE PULSE PROPAGATION IN AIR BREAKDOWN ENVIRONMENT

Kim, J., Polytechnic Univ., USA; Kuo, S. P., Polytechnic Univ., USA; Kossey, Paul, Phillips Lab., USA; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 9 p; In English; Sponsored by AFOSR Contract(s)/Grant(s): NAG5-1051; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

It is shown that ionization occurs wherever the field intensity of the pulse exceeds the local breakdown threshold field of the background air. The produced plasma then attenuates the pulse and gives rise to a tail erosion phenomenon that plays the primary role in limiting the energy transfer of the pulse from source to destination. A theoretical model describing the propagation of an intense microwave pulse in an air breakdown environment is developed that includes the possible focusing effect introduced by either using phase array antennas or the other arrangements. The self-consistent description of the propagation process is provided by a set of two modal equations. These include a continuity equation (Poynting's equation) for the

energy density of the pulse and a rate equation of the electron density. A forward wave approximation is used to simplify Poynting's equation, and a semiempirical formula is used for the ionization frequency, $\nu(\text{sub } i)$. This frequency provides the coupling between the two modal equations, and is used to express the electron rate equation explicitly. In terms of the relevant parameters of the atmosphere, these two equations are normalized for numerical analysis of pulse propagation in the atmosphere. The dependencies of the propagation characteristics of the pulse on intensity, frequency, width, and shape of the pulse are determined. The numerical simulations lead to a useful empirical relation $p(\exp 3)w = \alpha = \text{constant}$, where p and w are the incident power and width of the pulse and α depends on the percentage of pulse energy transferred from the source point to a destined position. The density distribution of the pulse's self-generated plasma is also evaluated. The results also show that for ionization caused by a single unfocused microwave pulse transmitted upwards from the ground, the maximum electron density produced at, for example, 50 km altitude is limited by the tail erosion effect to below $10(\exp 6) \text{ cm}(\exp -3)$. Repetitive pulse and focused beam approaches are also examined. Both approaches can increase the maximum electron density by no more than an order of magnitude. A scheme using two obliquely propagating pulses intersecting at the destined height, e.g. 50 km, is considered. It is shown that the electron density generated at the lowest intersecting position can easily reach a value of $6.6 \times 10(\exp 8) \text{ cm}(\exp -3)$, which is considered to be high enough for artificial ionospheric mirror (AIM) application.

A REVIEW OF NONLINEAR ELECTROMAGNETIC PROPAGATION EFFECTS

Lovetri, Joe, University of Western Ontario, Canada; Wartak, Marek S., Wilfrid Laurier Univ., Canada; Siushansian, Riaz, University of Western Ontario, Canada; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 9 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

It is well known that the presence of intense electromagnetic waves in media which is normally linear will have the effect of producing a nonlinear constitutive relation ($D = \epsilon(\text{E})E$). This paper reviews the fundamentals of nonlinear electromagnetic wave propagation with the goal of trying to coalesce the main features of this type of problem. The features of these important nonlinear effects are summarized and the way in which they manifest themselves mathematically into Maxwell's equations is reviewed. For example, in fiber optics the nonlinearities in the permittivity of the fiber have extreme consequences for the governing propagation equations (a nonlinear Schroedinger equation is derived). We identify important nonlinear mechanisms and analyze their basic physical contents. For that purpose many important analogies between propagation of intense nonlinear pulses in optical fibers and microwave pulses in the atmosphere are drawn and analyzed. The applications wherein these effects arise are then surveyed, some of these being intentional while others may be unwanted. The resulting nonlinear effects in fiber optics applications are very interesting (soliton propagation) and of practical importance in transoceanic telecommunication. Generation, detection, and propagation of optical solitons has been demonstrated over distances as long as 15,000 km. The soliton laser, which utilizes Kerr nonlinearity in optical fiber, has also been demonstrated. In the case of the propagation of radio waves and microwaves through the ionosphere these effects may be undesirable but can be put to use in order to localize or columnize the beam. Thus, for the production of soliton waves in fiber optics and for the columnization of high power microwaves, the nonlinearities are essential. Next, some of the modeling techniques which are available for some of the nonlinear problems are

surveyed and explained. Numerical results for nonlinear electromagnetic propagation are reviewed. Finally, future problems resulting from the inclusion of nonlinearities are addressed.

SPECTRAL VARIATION OF HIGH POWER MICROWAVE PULSE PROPAGATING IN A SELF-GENERATED PLASMA

Ren, A., Polytechnic Univ., USA; Kuo, S. P., Polytechnic Univ., USA; Kossey, Paul, Phillips Lab., USA; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 10 p; In English; Sponsored by AFOSR Contract(s)/Grant(s): NAG5-1051; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

A systematic study to understand the spectral variation of a high power microwave pulse propagating in a self-generated plasma is carried out. It includes the theoretical formulation, experimental demonstration, and computer simulations and computer experiments. The experiment of pulse propagation is conducted in a vacuum chamber filled with dry air (approximately 0.2 torr); the chamber is made of a 2 ft. cube of Plexiglas. A rectangular microwave pulse (1 microsec pulse width and 3.27 GHz carrier frequency) is fed into the cube through an S band microwave horn placed at one side of the chamber. A second S-band horn placed at the opposite side of the chamber is used to receive the transmitted pulse. The spectra of the incident pulse and transmitted pulse are then compared. As the power of the incident pulse is only slightly (less than 15%) above the breakdown threshold power of the background air, the peak of the spectrum of the transmitted pulse is upshifted from the carrier frequency 3.27 GHz of the incident pulse. However, as the power of the incident pulse exceeds the breakdown threshold power of the background air by 30%, a different phenomenon appears. The spectrum of the transmitted pulse begins to have two peaks. One is upshifted and the other one downshifted from the single peak location of the incident pulse. The amount of frequency downshift is comparable to that of the upshifted frequency. A theoretical model describing the experiment of pulse propagation in a self-generated plasma is developed. There are excellent agreements between the experimental results and computer simulations based on this theoretical model, which is also used to further carry out computer experiments identifying the role of plasma introduced wave loss on the result of frequency downshift phenomenon.

UPGRADING OF THE RF TUBES OF THE PRESENT STATE OF THE ART

Faillon, Georges, Thomson Tubes Electroniques, France; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 7 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Although basic studies are far from completion, the microwave levels requested for the vulnerability test benches are far below those expected on HPM weapons. At the same time, the main requirements of the test benches are accuracy and reliability, therefore the sources to be used can be derived from the existing high power sources commonly used in several fields such as radars, particle accelerators, thermonuclear fusion, etc. For example, the development of klystron amplifiers delivering 100 to 200 MW in S band with 1 microsec pulse length is in progress. In shorter pulses (10's of ns) relativistic magnetrons (below the X or C band) and BWO's (beyond the X band) begin to be easy to bring into operation. Nevertheless amplifiers seem more attractive because their pulses shapes, their frequencies and their phases are entirely controlled. The bandwidth is also an important technical characteristic. Devices such as pulse compressors upgrade existing tubes. The single cavity, plasma switch compressor trans-

forms for example a 50 kW 2 microsec pulse into 3 MW, 5 ns in X band and the same principle can be applied to provide up to 50 to 200 MW according to the frequency.

A laboratory for high level microwaves was studied and carried out by Thomson Shorts Systemes. This installation produced: strong powers ultra high frequency (1 GW Peak), and radiated strong fields. The possibilities of this installation allow the user to carry out strong tests of vulnerability in fields of high level microwaves, and to be used as technological demonstrator implementing strong pulsed voltages (1 MV) of strong currents (a few tens of kA) and large power radiated ultra high frequencies (1 GW).

RADIAL ACCELETRON: A NEW LOW-IMPEDANCE HPM SOURCE

Arman, Moe Joseph, Phillips Lab., USA; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 11 p; In English; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Under a grant from the National Research Council and in collaboration with the Phillips Laboratory, the author was tasked to explore and analyze the proposed concept of using transit-time effects in a coaxial geometry to develop a low-impedance HPM source that uses no external magnetic field and no confining foils. This source will work in the 1-20 GHz range and will have a power output of no less than 1 GW. The input will be a low-voltage dc pulse of only 350kV or less with a flat top of approximately 200ns. The dc pulse is launched into a coaxial structure that is the diode, the oscillator, and the buncher all in one. Strong impedance mismatch between the diode section and the body of the device provides enough reflection to have a well defined coaxial cavity of high Q to support cavity characteristic modes. Electrons are emitted from the inner conductor of the structure and as they accelerate towards the anode they interact with a selected characteristic mode of the structure, on the average losing kinetic energy to the mode. This process continues until the RF fields are strong enough to modify the transit time away from the optimal value thus leading to saturation. The source offers significant improvements in power, repetition rate, size, and efficiency. Because of the coaxial structure, the diode impedance may be reduced to a few ohms thus allowing larger input and output powers. With no foils to erode, the only thing limiting the repetition rate is the vacuum ability, and since there is no external magnetic field required, the device is simple, lightweight and inexpensive.

sive. Because of the strong bunching the efficiency is high. As is the case with all transit-time oscillators, the signal is stable and monochromatic. The device may be used as a buncher or as an oscillator. In what follows I present the progress made so far and show that all goals set forth in this project are achieved. In addition it is shown that the gated emission of electrons, a process basic to high power rf-amplification, is a natural by-product of the mechanism used in this device.

The synthetic aperture technique, together with a procedure to make the wide band pulses, enables achievement of high resolution bidimensional images of the ground with a side-looking airborne radar system. With some kinds of transpositions, such images, gathered during an airborne campaign, are significant of results in a space-based context.

BISTATIC STUDY OF THE POLARIMETRIC BEHAVIOR OF THE OCEANS ETUDE BISTATIQUE DU COMPORTEMENT POLARIMETRIQUE DES OCEANS

Daout, F., Nantes Univ., France; Khenchaf, A., Nantes Univ., France; Hurtaud, Y., Centre d'Electronique de l'Armement, France; Saillard, J., Nantes Univ., France; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 13 p; In French; See also 19960007226; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper covers the general topic of remote sensing and radio propagation above the sea surface. A study concerning scattering methods on the oceanic surface is first presented, followed by the search of the polarimetric signature of the sea surface, as a function of the observation parameters and some theoretical scattering models. A technique of polarimetric optimization is finally developed to increase the reliability of the radio link as well as to improve the radar accuracy.

With the proliferation of efficient, accurate, range-dependent propagation models, the largest remaining challenge in shipboard environmental assessment is obtaining high-resolution atmospheric data for use in these models. Due to the difficulty of acquiring data in all directions from a ship, it is particularly important to establish what horizontal separation between atmospheric profiles is adequate for accurate shipboard assessment. It is equally important to determine the minimum acceptable resolution in the vertical direction. In order to begin to investigate these spatial sampling requirements, this paper examines two sets of high-resolution atmospheric data collected along the east and west coast of the U.S. These data were collected by an instrumented helicopter in support of U.S. Navy propagation experiments and tests. The sampling necessary to represent significant atmospheric structures is discussed, and an accurate propagation model is used to examine the sensitivity of propagation predictions to vertical and lateral data resolution. Results are presented for 3 and 10 GHz to examine the frequency dependence of resolution effects.

MODELING NONPERFECT REFLECTION FROM THE SEA FOR RANGE-DEPENDENT DUCTING CONDITIONS

Hitney, Herbert V., Naval Command, Control and Ocean Surveillance Center, USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 6 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper describes an approximate method to account for nonperfect reflection from the sea that uses a simple technique to modify a parabolic equation (PE) model based on sine fast Fourier transforms (FFT's). Although the method is an approximation, it gives good results compared to other more rigorous models, and is very efficient. Comparisons of results for ducting conditions that are homogeneous with range using the approximate, waveguide, and mixed transform PE methods are presented to evaluate the approximate method. The approximate method is easily extended to range-dependent ducting and roughness conditions likely to be encountered in coastal

environments. to evaluate these cases, a comparison is made of approximate method results and results from a mixed-transform PE model for vertical polarization.

A PROPAGATION-BASED MODEL OF TERRAIN EFFECTS FOR SHIP-BOARD RADAR APPLICATIONS

Reilly, J. P., Johns Hopkins Univ., USA; Lin, C. C., Johns Hopkins Univ., USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 12 p; In English; See also 19960007226; Sponsored by US Navy AEGIS Shipbuilding Program; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

In this paper, a site-specific approach is presented to characterize terrain and target visibility and terrain clutter as seen by a ship-board radar in a coastal environment. The method takes into account the location of the ship, the particular terrain topography, the radar parameters, and the propagation effect. The method incorporates refractive index models of the atmosphere surrounding the radar, an optical ray-trace model, an electromagnetic parabolic equation model, and a data base of terrain elevations. The model can simulate illumination and shadow regions of both surface clutter and elevated targets. Simulated clutter results are shown to compare favorably with clutter data measured at S-band. This correspondence is evident in geographic patterns and statistical distribution of clutter on directly illuminated terrain surfaces.

OPERATIONAL SUPPORT FOR A RANGE-DEPENDENT RADIO PROPAGATION MODEL

Cook, John, Naval Research Lab., USA; Vogel, Gerard, Naval Research Lab., USA; Love, Gary, Naval Research Lab., USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 8 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

The emerging new standard in the U.S. Navy for range-dependent radio propagation assessment is the Radio Physical Optics (RPO) model developed at the Naval Command, Control and Ocean Surveillance Center, RDT&E Division (NRaD). RPO allows one to compare the expected radio propagation loss field as a function of height along a desired bearing, provided the atmospheric propagation conditions are specified along the path. This paper describes an architecture being developed to operationally support RPO. In developing this architecture, a number of unique constraints and considerations have been dealt with to provide RPO with cross-sections of atmospheric propagation conditions. First, forecast grids from a mesoscale weather data assimilation/prediction model are accessed to provide the best estimate of the current and future refractive and meteorological conditions over the area of interest. Based on conditions near the surface, high-resolution profiles of refractivity in the evaporation duct are calculated and appended onto the bottom of the model forecast profiles. This completes the specification of refractivity down to the sea surface. These refractivity profiles are then processed by a unique algorithm that matches similar refractivity structures from profile-to-profile and reformats the data to support the indexing scheme required by RPO. After RPO has been run, the propagation loss results can be displayed and thresholded to provide expected coverage against specific targets. An example will be shown where multiple RPO runs are used to suggest positioning of available assets to maximize coverage.

REFRACTION EFFECTS ON EO SYSTEM DETECTION RANGES IN COASTAL ENVIRONMENTS

Dion, Denis, Defence Research Establishment Valcartier, Canada; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 9 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Atmospheric refraction can significantly affect the detection range performances of electro-optical (EO) systems against low-level targets in coastal environments. Negative air-sea temperature difference (ASTD) conditions, which produce subrefraction, impose an absolute limit of detection range shorter than the terrestrial horizon, while positive ASTD conditions, which produce superrefraction, allow radiation to propagate beyond the horizon. For subrefraction conditions, an approximate formula is given for estimating the detection range limit as a function of ASTD, wind speed and sensor-target elevations. Under superrefraction, the detectability is degraded by the refraction-induced ray spreading near the sea surface. This refraction loss, which depends on the weather conditions and the sensor-target elevations, is discussed.

COMPARISON OF SIMULTANEOUS 3-5 AND 8-12 MICRO TRANSMISSION MEASUREMENTS NEAR THE OCEAN SURFACE

Bull, H. T., California State Univ., USA; Jensen, D. R., Naval Command, Control and Ocean Surveillance Center, USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 6 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

A comparative transmissometer has been developed for evaluating the simultaneous transmission characteristics for near ocean surface transmissions in the 3-5 micron and 8-12 micron bands. This transmissometer is a special purpose instrument designed for simultaneously measuring the changes in transmission of the 3-5 micron and 8-12 micron transmission bands. The transmissometer has been operated over the San Diego Bay, California, to determine the transmission characteristics for near ocean propagation paths. Observed propagation characteristics for both the 3-5 micron and 8-12 micron bands are compared and discussed as a function of existing sea states and meteorological conditions. The observed transmission characteristics for the two wave bands are compared with LOWTRAN calculations. Rapid fluctuations in received signal strength, their power spectra, and correlation coefficients are also discussed.

IMPACT OF COASTAL ENVIRONMENT ON POINT TARGET DETECTION

Stein, K., Forschungsinstitut fuer Optik, Germany; Kohnle, A., Forschungsinstitut fuer Optik, Germany; Schubert, W., Forschungsinstitut fuer Optik, Germany; Jantzen, R., Forschungsinstitut fuer Optik, Germany; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 10 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

It is still difficult for a sensor system to detect low flying anti-ship missiles over long distances with high detection probability and low false alarm rates. In continuation of the work in this subject area concerning infrared (IR) sensor systems the FGAN-FIO participated in the MAPIP trial of NATO AC/243 (Panel 04/RSG.08) with two infrared (IR) / visible (VIS) camera systems set-up on the Katwijk coast in The Netherlands. Two main types of measurements were performed. Observations of a fixed target mounted on a mast on the Meetpost Noordwijk platform 5.6 miles off the Katwijk coast, and tracks of planes, especially of the inbound flights of a Piper Navajo, chartered by the US-NCCOSC. Initial analysis results of the temporal and spatial behavior of the fixed and moving targets, especially the two engines of the Piper Navajo, are given. In addition, experimentally determined signal-to-noise ratios from IR imagery are compared with calculations

using the FGAN-FIO thermal range model for point target detection (TRP). The correspondence is quite good. It was possible to track the Piper Navajo up to 13 nautical miles (nmi) in the 8 - 12 micron waveband, less far in the 3 - 5 micron wavelength region. This was partially due to the lower sensitivity of the used sensor in this waveband. The two engines of the approaching plane were resolved at 8 nmi. Steps have been undertaken to analyze the handle of extremely close multiple targets (as the two Navajo engines seen at long distance) by different image processing algorithms. One example is given where bispectrum analysis is used to clearly resolve the two Navajo engines at long distances. Forschungsinstitut fuer Optik (FIO, Research Institute for Optics) presents first results from their participation in the MAPTIP measurement campaign.

This paper presents some results obtained by Canada's Defence Research Establishment Valcartier (DREV) during the Marine Aerosol Properties and Thermal Imager Performance (MAPTIP) trial off the North Sea coast of The Netherlands during October 1993. Our study of refraction effects in the Marine Boundary Layer (MBL) in both the visible and infrared (IR) wavelength bands produced a large quantity of excellent experimental data. Along with data obtained from previous campaigns in both Canada and Germany, this data set is being used to test the validity of the WKD and the Wavy WKD (WWKD) models developed by DREV. These early results from the recent MAPTIP trial have shown that in general the predictions of the WWKD model agree remarkably well with the experimental data.

The performances of most systems operating at RF and millimeter waves can be seriously affected by propagation effects. That is the reason why NATO established the Research Study group No. 8 (RSG8) within Panel 3 (physics and electronics) of Defense Research Group (AC 243), with its Propagation Subgroup (PSG) responsible for the propagation aspects. Comparison of mm and other wavelengths was to be considered. In maritime and coastal environments, the use of such wavelengths for various military applications like anti-ship seekers, fire control radars, ship to ship communications or Electronic Support Measurements (ESM) led to the setting up of specific measurement campaigns; the last three are reported hereafter. The first two experiments used facilities close to Lorient, on the Atlantic coast, and Toulon, on the Mediterranean coast of France, with the purpose of documenting the refractive effects for medium range over

the horizon paths. These experiments were referred to as Lorient 89 and Toulon 90 campaigns, are described in this paper, and some typical results are presented. The latest cooperative work of RSG8/PSG took place recently (fall 1993) near Lorient, on a line-of-sight 10 km path over seawater. This experiment, referred to as Lorient 93 campaign, was devoted to the analysis of phase-front distortions due to multipath along with refractive effects, and to the assessment of performances for naval systems like short range tracking radars. Analysis of the data, either on a statistical base or as specific case studies, is being performed presently, but some early typical results will be given in this paper after a detailed description of the experiment. The performance of radar and infrared systems in a maritime environment is strongly dependent on the conditions of the atmosphere and the sea surface. In the autumn of 1993 an experiment was set up by the NATO Research Study Group AC/243 Panel3/RSG21 to collect propagation data at a line-of-sight propagation path. The purpose of the experiment was to gain knowledge about the behavior of the path loss and angle of arrival of the signals. This paper presents the results of the Dutch contribution to the experiment and a comparison of the measurements with model predictions. For radar in the line-of-sight situation the propagation is dominated by the multipath interference and influenced by ducting. Predictions performed with the propagation model PCPEMC and the Bulk-CELAR duct model show satisfying results for the position of the nulls, if wind speed and wave height are taken into account. Using the data of this experiment, a synergism between radar and IR angle of arrival could not be proven.

MODELING THE VERTICAL PROFILES OF THE INDEX OF REFRACTION AND (C(SUB N))(EXP 2) IN MARINE ATMOSPHERE MODELISATION DES PROFILS VERTICAUX D'INDICE DE REFRACTION ET DE CN2 EN ATMOSPHERE MARINE

Claverie, Jacques, Ecoles de Coetquidan, France; Hurtaud, Yvonick, Centre d'Electronique de l'Armement, France; Defromont, Yannick, Ecoles de Coetquidan, France; Junchat, Alain, Centre d'Electronique de l'Armement, France; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 11 p; In French; See also 19960007226; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

The determination of the conditions of propagation, for systems evolving/moving in the CLSO (Boundary layer of Oceanic Surface), requires the knowledge of the vertical profile of index of refraction. From simple weather measurements, the model PIRAM (Profiles of Index of Refraction in Atmosphere Navy) makes it possible to calculate this profile starting from the vertical profiles of temperature and moisture. PIRAM takes again, with the help of some modifications, the step followed in the Bulk-CELAR model conceived initially for the radio frequencies. Calculations from now on were extended to the optical field. PIRAM also allows the modeling of the vertical profile of the structural parameter of the index of refraction of the air (C(sub n))(exp 2). This new modeling will have to be validated by experimental data. Near the coasts, the knowledge of the vertical profiles is however not always sufficient, because in particular of the horizontal inhomogeneity of the channel of propagation.

AN OVERVIEW OF AN INTENSIVE OBSERVATION PERIOD ON VARIABILITY OF COASTAL ATMOSPHERIC REFRACTIVITY

Paulus, Richard A., Naval Command, Control and Ocean Surveillance Center, USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 6 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper is an overview of an experiment called Variability of Coastal Atmospheric Refractivity (VOCAR). VOCAR was designed to be conducted under a larger program called Coastal Variability Analysis, Measurements, and Prediction and is a multi-year experimental effort to investigate the variability of atmospheric refractivity with emphasis on the coastal zone. The experiment is being conducted jointly with the Naval Air Warfare Center Weapons Division, Point Mugu, CA, the Naval Research Laboratory, and the Naval Postgraduate School. In addition, the National Oceanic and Atmospheric Administration Environmental Technology Laboratory and Penn State University/Applied Research Laboratory are participating in the measurement phase of VOCAR. The propagation measurements being made during VOCAR consist of monitoring signal strength variations of VHF/UHF transmitters in the southern California coastal region. Corresponding meteorological measurements are made during routine, special, and intensive observation periods. During an intensive measurement period from 23 August to 3 September 1993, radio data were collected at two receiver sites and meteorological data were collected from three profiler sites, eight radiosonde sites, three aircraft, and numerous surface weather sites. Samples of the data will be shown.

EFFECTS OF SPATIAL AND TEMPORAL VARIABILITY OF ATMOSPHERIC REFRACTIVITY ON THE ACCURACY OF PROPAGATION ASSESSMENTS

Rogers, L. Ted, Naval Command, Control and Ocean Surveillance Center, USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 9 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Meteorological measurements indicating range dependent refractive structures have been documented by several observers. A central concern arising from these observations is the affect the assumption of horizontal homogeneity has on the accuracy of propagation assessments, where accuracy is defined as the difference between estimated and measured propagation loss. Complicating the discussion of variability are conflicting goals for propagation model performance versus propagation assessment system performance. With the former, the goal is to minimize error at the time of environmental observation used for the model inputs. With the latter, the goal is to minimize error over the time of use of propagation estimates, a period of time that is often measured in hours with the current level of environmental sensing technology. With these considerations in mind, the effect of spatial and temporal variability of the atmospheric refractive structure on real-time or nearly real-time radio frequency (RF) propagation assessment system performance is examined.

REFRACTIVE VARIABILITY DURING VOCAR 23 AUGUST TO 3 SEPTEMBER 1993

Helvey, Roger A., Naval Air Warfare Center, USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 7 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Measurements of the lower atmosphere from the southern California coastal area were obtained from a number of sources during the 23 Aug. - 3 Sep. 1993 VOCAR Intensive Observation Period (IOP).

Data from high-resolution radiosondes, surface stations, aircraft and weather satellite have been collected for use in identifying mesoscale atmospheric phenomena and related refractive features. Spatial and temporal variations in the height of the elevated duct associated with these phenomena are a major factor in determining refractive conditions in this region. An automated isentropic cross-section analysis tool is being applied to the upper-air data, to facilitate correlation with analyses of data from satellite imagery and the other sources.

USE OF SATELLITE IMAGERY AND OTHER INDICATORS TO ASSESS VARIABILITY AND CLIMATOLOGY OF OCEANIC ELEVATED DUCTS

Helvey, Roger, Naval Air Warfare Center, USA; Rosenthal, Jay, Naval Air Warfare Center, USA; Eddington, Lee, Naval Air Warfare Center, USA; Greiman, Paul, Naval Air Warfare Center, USA; Fisk, Charles, Naval Air Warfare Center, USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 14 p; In English; See also 19960007226; Copyright; Avail: CASI; A03, Hardcopy; A03, Microfiche

Much of the world's ocean area is overlain by persistent elevated ducting due to a strong super-refractive gradient at the top of the marine layer. Several techniques are used to describe characteristics of the elevated duct on climatological, synoptic and local scales. In addition to statistical analysis of radiosonde databases, these techniques include subjective and objective applications of satellite imagery, computation of a duct height index from surface and upper level numerical analyses or forecasts, and various other indirect meteorological indicators of ducting. Refractive statistics from worldwide coastal, island and ship radiosonde profiles reveal a widespread diurnal variation in duct occurrence believed related to day-night changes in marine stratus/stratocumulus cloud amounts. Incorporation of this diurnal behavior, together with relationships found between elevated duct characteristics and conventional parameters suggest a basis for generation of improved worldwide oceanic elevated duct climatology from historical gridded surface upper-air analyses. The climatology would be in a gridded format, calibrated against climatological summaries from radiosondes to enable estimates of conditions for arbitrary locations, dates and times. Techniques for synoptic and mesoscale inference of elevated duct behavior are demonstrated using satellite imagery and synoptic indicators. Geostationary satellite imagery obtained during VOCAR in 1993-4 revealed synoptic and mesoscale cloud features depicting space/time variability over the eastern Pacific Ocean and adjacent coastal areas. The variability was related to large-scale air mass changes and weather systems; the development, dissipation and translation of coastal eddies in the marine layer; and diurnal land/sea breeze influences in the coastal zone.

MESOSCALE MODELING OF REFRACTIVE CONDITIONS IN A COMPLEX COASTAL ENVIRONMENT

Burk, Stephen D., Naval Research Lab., USA; Thompson, William T., Naval Research Lab., USA; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 7 p; In English; See also 19960007226; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

A mesoscale model was run in a data assimilation cycle throughout the 12-day period of the Variability of Coastal Atmospheric Refractivity (VOCAR) experiment's Intensive Observing Period (IOP). A developing synoptic low, a mesoscale eddy, sea-land breezes, mountain-valley winds, and coastal low-level jets (LLJs) are some of the phenomena modeled, and to some extent, observed during VOCAR. Impacts of these processes on the marine atmospheric boundary layer (ABL) and microwave refractivity are highlighted in this paper. From August 23 to September 3, 1993 the IOP of the VOCAR

experiment was conducted in the Southern California bight from Point Conception to San Diego. This experiment was designed to observe the mesoscale structure of the ABL in the bight so as to accurately characterize the temporal and spatial variability of the microwave refractivity field. Analyses or forecasts of propagation conditions (e.g., surface-based or elevated trapping layers; exist of over-the-horizon propagation, etc.) require accurate depiction of the depth and structure of the ABL (particularly vertical gradients in temperature and moisture at the ABL top). Numerous special observations were made during the IOP and are used to elevate model performance.

Coastal area propagation and meteorological measurements have been studied along with atmospheric mesoscale modeling. Simultaneous propagation data from three consecutive links have been compared with measured and modeled meteorological data from a part of the Norwegian coast at about 65 deg latitude. The results show a close relationship between refractivity gradient, obtained by meteorological data, and multipath activity on the links. The mesoscale model does also give valuable information on the spatial and diurnal time dependency of refractivity gradients at the vicinity of ground as well as at various heights above the ground.

A MICROWAVE PROPAGATION MODEL COUPLED TO AN AIR MASS TRANSFORMATION MODEL

Grandin, G. E., Swedish Air Force, Sweden; AGARD, Propagation Assessment in Coastal Environments; Feb 1, 1995, 5 p; In English; See also 19960007226; Copyright; Avail: CASI; A01, Hardcopy; A03, Microfiche

Since 1985 a project in order to improve microwave propagation forecasts has been run in the Swedish Military Weather Service. The purpose has been to tests if there are computer-based models that are more useful than earlier manual methods. Until now two different kinds of models have been tested: The first one is a simple refractive index model for use onboard warships. The second kind of model is a refractive index model coupled to a one-dimensional boundary layer model connected to a horizontal trajectory in order to describe horizontal advection. The result is presented by ray tracing diagrams in order to give advice for tactical decisions at military aircrafts, warships and radar stations. Experiments with those two models have been made mainly over the Baltic Sea. During 1987-1992 the 'simple' model was tested onboard a warship. During the same period the other model was tested on nine sites in Sweden. There have been three 'intense' periods where extra efforts in personnel, measurements and verifications were made. The experiments showed that computer-based radar range forecasts are only usable in the Baltic Sea if: (1) there is input data with high quality; (2) the weather situation is homogeneous; and (3) the operators are educated.

Global maps of super-refraction and duct statistics based on the analysis of radiosonde data have, for many years, been used to characterize the effects of climate in statistical radiowave propagation models. This paper describes a new analysis based on a more recent and more extensive dataset. The sources of radiosonde data and our data reduction and validation strategy are discussed, and the statistical parameters of interest for super-refracting and ducting layer statistics are introduced. Contour maps of these parameters are given for the European region; comparisons with earlier data highlight some of the problems involved in this type of study. Comparisons of high and low resolution data analyses for the coastal site of Hemsby in the UK are made, and the influence of the boundary layer on surface duct statistics discussed. Some conclusions are drawn on the usefulness of radiosonde data for the mapping of refractivity parameters.

In June 1992, IR/RF propagation experiments were conducted over the North Sea, at about 10 km SW from the German island of Sylt. The experiments were a tri-lateral cooperation between institutes from Germany, Canada and The Netherlands, organized by the TNO Physics and Electronics Laboratory. The objective was a study on the complementarity of IR and radar detection systems. In this contribution we report on the characterization of the propagation environment by the TNO Physics and Electronics Laboratory. This includes aerosol and lidar measurements to determine the extinction properties throughout the marine atmospheric boundary layer, as well as measurements of humidity and temperature profiles in the marine atmospheric surface layer to determine refractivity profiles. Temperature and humidity profiles were measured from a jack-up barge 'Hubinsel Barbara' and on a mast. The sensors were mounted such that profiles could be measured from close to the sea surface, taking into account tidal effects and waves of 1.5 m, to height of 10 m on the mast and 35 m on the platform. The platform data are often perturbed. Therefore, in the analysis we focussed on the temperature and humidity profiles from the mast. Effects of sensor height, wind speed and thermal stratification were considered. Deviations from the logarithmic behavior have been observed. These are mainly ascribed to coastal influences, based on consideration of the height dependence and the effects of thermal stability. We conclude that in off-shore winds non-equilibrium situations often exist at the sensor locations, with an internal boundary layer that distorts the profiles.

This conference demonstrated that there are major C3I developments for the various international air forces underway, particularly in the USA (Theater Battle Management), in France (SCCOA), and at NATO (ACCS). These C3I systems (in effect, 'system systems') combine all the real time (surveillance, air mission control) and deferred functions (force planning and management) at a very high level of complexity. One of the problems has been how to organize,

manage, and control data flow between the complex elements of these systems. Tools are now being developed with this in mind. Another problem is that, although it is cost effective to use off-the-shelf components in the systems design, this process in itself creates a number of trade-off problems with regard to the system's conformity to specifications. The discussions and presentations of this conference were concerned with the following main issues: Requirements and trends in architecture; situation assessment; decision aids for planning, tasking, and execution, and techniques and technologies.

The decision to create such a program for SCCOA was made on February 15, 1989. The author discusses the rationale for the creation and growth of the program. The article emphasizes the advantages of having an open and evolving system. Mentioned are the new specific requirements for the future of aviation command and control systems (installation of 23 cm radar units for civil aviation; high frequency over the horizon radars for the S and L bands, particularly for small radar cross section targets; and an AWACS system for low altitude targets). A systems approach will be required for the detection area in order to achieve better radar coverage and operation in emergencies. Data produced by the detection equipment will be transmitted to the control and command center of the aviation operations.

This article discusses the longterm aspects of command, communications, and control as they relate to Air Force strategic planning. The author begins by discussing the different characteristics of the present programs including the following: the growing significance of software in major systems; the evolution of software packages rather than fundamental growth; the fact that after the current programs have been completely computerized that there will be only minor additions and changes as required to these systems; the fact that there are approximately thirty different systems that can be identified which must be able to operate with one another; and that the equipment, the software, and the interfaces between the various softwares for these systems are becoming increasingly standardized. The author then analyzes future trends ten to twenty years beyond the time period covered by the present programs.

AIR FORCE C3I ARCHITECTURE CONCEPTS

Crochet, M., Aerospatiale, France; Oct. 1995; 4p; In English; See also 19960016897; Copyright Waived; Avail: CASI; A01, Hardcopy; A03, Microfiche

The purpose of this paper is to discuss architectural concepts as they apply to a system, of which the complexity is more than simply the addition or the connection of subsystems. This is the way that the large C3I systems for the Air Defence and Air Operations must be designed, since the systems control a large set of planning, tasking, mission preparation, mission control, intelligence, and communications that overlap in this complex set of a 'System of Systems.' This article discussed the SCCOA environment, new functions (concepts) in SCCOA, the architecture, the architects, those people involved in the development and use of the system, the tools used in developing the architecture, and the management of the system.

A TECHNICAL MANAGEMENT STRUCTURE FOR THE EVOLUTION OF TACTICAL AEROSPACE C3I SYSTEMS

McCay, Brian M., Mitre Corp., USA; Oct. 1995; 10p; In English; See also 19960016897; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

A technical management structure using Model-Based Systems Engineering (MBSE) concepts and implemented via an integrated suite of tools is recommended to manage the evolution of tactical aerospace C3I systems. A system-of-systems (S2) engineering perspective is advocated to identify processes, methods, and tools that support the capture, analysis, and management of these systems. An integrated systems engineering environment (ISEE) is introduced as the mechanism used to capture, store, and generate the information necessary to manage change across tactical aerospace C3I systems. Work currently being performed to manage change of the Air Warning Mission C3I systems within the Integrated Tactical Warning/Attack Assessment (Integrated TW/AA) S2 is discussed to show how MBSE concepts are currently being used. Extensions of this work are presented in terms of an evolving tactical aerospace C3I systems architecture and the inclusion of other tools. Finally, advances in enabling technologies, methods, and tools are mentioned to suggest directions of how to fully develop a tactical aerospace C3I systems ISEE.

HORIZON: AN ARCHITECTURE MANAGEMENT AND C4I CAPABILITIES PLANNING PROCESS FOR THE UNITED STATES AIR FORCE

Cookerly, David H., Department of the Air Force, USA; Buckley, David I., Mitre Corp., USA; Boyle, Eugene J., Jr., Mitre Corp., USA; Oct. 1995; 16p; In English; See also 19960016897; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

A methodology for managing Command, Control, Communications, Computers, and Intelligence (C4I) interoperability problems in a multi-mission environment is presented. The effort, designated Horizon, was sponsored by the USA Air Force (USAF). It is a disciplined top down process for managing and directing architectures starting at a high level. The essential elements of interoperability are defined. Mission operations boundaries are formulated to serve as a framework for construction of top level and mission level views of the C4I elements. Information flow between C4I elements is described, and the combination of the views and the interoperability attributes are organized into a database. Commercial-off-the-Shelf (COTS) software was used to develop a tool, designated Horizon Link, to support the process. The database may be expanded to accommodate specific user needs and to support specialized analyses. The use of the database to support specialized analyses. The use of the database to support a communications systems analysis within the framework of the defined C4I interoperability model is described.

SECURITY OF COMMAND SYSTEMS LA SECURISATION DES SYSTEMES DE COMMANDEMENT

Velu, Jean-Pierre, Societe d'Applications Generales d'Electricite et de Mechanique, France; Oct. 1995; 8p; In French; See also 19960016897; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The security of command information and communication systems is a necessity because these systems must fully and exactly carry out the mission entrusted to them. Many examples have shown that when security is neglected, the risks incurred could be catastrophic, especially in a crisis. The sensitive information involved in these situations is stored in the databases of these interconnected systems. Consequently, an attack on one of the interoperable SIC network units could be harmful to the entire group of systems and could even, in the worst case, paralyze the entire network. The defense against such attacks consists of controlling access to the sensitive data, as automatically as possible. In other words, surveillance over the subjects and objects of security must be carried out in conformity with a previously established discipline, 'the security policy', of the system in question. This security policy, which must be tested for certain assurance levels for implementation, is prioritized in terms of the security required for: computer retrieval that pertains to data access; data transmissions; and physical access. Dealing with all of these aspects exceeds the scope of the present presentation, in such, that we will limit our discussion to the examination of the typical situations that are often encountered in the integration of commercial products, the restoration of systems, and the interoperability of the SIC systems. Although we will not examine multi-level use systems, we will discuss the security of databases and the identification/authorization process, which are two essential points of security.

APPLICATIONS OF MULTISENSOR DATA FUSION TO TARGET RECOGNITION

Moruzzis, Michel, Thomson-CSF, France; Colin, Nathalie, Thomson-CSF, France; Milhem, Gilbert, Thomson-CSF, France; Oct. 1995; 10p; In English; See also 19960016897; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Target Recognition, which is a key function for ensuring the successful execution of conflicts and wars, will be based on multi-sensor data fusion. The objective of this paper is to highlight some aspects of multisensor data fusion applied to target recognition in the aim of defining an operational system. This paper gives a description of a multisensor system and the processing architecture which can be used for simultaneous target recognition and tracking. Basic fusion techniques, such as Bayesian Inference, Evidence Theory, and Fuzzy Logic, are then introduced with some practical results presented to illustrate these techniques. A data processing architecture, which includes both tracking and recognition functions, is presented and the respective merits of the conventional techniques are discussed in regards to the different processing functions.

DISTANCE BASED RANGE PROFILE CLASSIFICATION TECHNIQUES FOR AIRCRAFT RECOGNITION BY RADAR: A COMPARISON ON REAL RADAR DATA

vanderHeiden, R., Organisatie voor Toegepast Natuurwetenschappelijk Onderzoek, Netherlands; Groen, F. C. A., Amsterdam Univ., Netherlands; Oct. 1995; 8p; In English; See also 19960016897; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Aircraft identification is essential in any air-defense scenario. Without a robust classification capability, no effective threat evaluation can be performed. A prominent aircraft recognition technique is based on the exploitation of a one-dimensional image of a target, a range, profile. In this paper, we employ four different classification tech-

niques, all based on shift invariant distances, and a method to compare them. Two of the techniques are based on Radial Basis Functions for which a novel technique to optimize the number of free parameters is presented. The application is one real radar data, where a true separation between train and test profiles is accomplished. The classification results are encouraging. As an example, a qualitative statement is given about the best of the four classifiers to be used in combinations of two scenarios and four applications.

A Decision Tool for air defense is presented. This Decision Tool, when provided with information about the radar, the environment, and the expected class of targets, informs the radar operator about detection probabilities. This assists the radar operator in selecting the optimum radar parameters. This newly developed computer program, PARADE, is presented along with its future applications for use with radar operator parameter selection.

MULTIPLE HYPOTHESIS TRACKING VERSUS KALMAN FILTER WITH NEAREST NEIGHBOR CORRELATION. PERFORMANCE COMPARISON

Graziano, A., Alenia Spazio S.p.A., Italy; Miglioli, R., Alenia Spazio S.p.A., Italy; Farina, A., Alenia Spazio S.p.A., Italy; Oct. 1995; 12p; In English; See also 19960016897; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Multi-target tracking systems in operational use today generally adopt standard Kalman filter techniques, coupled with a maneuver detector to introduce some kind of adaptivity, and nearest neighbor (NN) correlation with a plethora of heuristics to improve the performance of the system. Through Monte Carlo simulations, the performance of a multiple hypothesis multi-target tracking algorithm were evaluated in the terms of the probability of correct association of a track to a target. The performance of a Kalman filter plus NN issued as reference. Results are presented for a number of study cases related to several operational situations of interest (e.g. up to eight targets undergoing maneuvers). A preliminary evaluation of the processing time ensures that the MHT algorithm can be implemented in modern computers having adequate processing power.

The JTIDS Joint Program Office (JPO) has been on the leading edge of the large scale multi-service, multi-platform, multi-mission JTIDS network design for several years. Large scale network design studies conducted by the JPO have shown that if JTIDS is used efficiently and appropriately, it can meet expanding user and functional requirements, including multi-national operations. However, increasing reliance on JTIDS for theater communications will require a continued effort to develop more efficient ways to use it.

An in-depth knowledge of the characteristics of the propagation medium and how they should/could be modified is essential in order to obtain more efficient sensors for aerospace systems. During the symposium the effects of environmental factors on the different disciplines relating to EW were widely analyzed, and all relevant aspects were considered including among others: the effect of interference in the ionosphere on various satellite systems, and the propagation mechanisms affecting countermeasures against EO and laser systems; the layering of appropriate paints as a means of protecting airbase structures in more than one band, as well as camouflage as a measure against radar sensors; and the disruptive potential of high-power microwaves, and the exploitation of SMART munitions. Considering the problem of reduction of aircraft signature, evidence was provided that it is not possible to achieve this by an accurate definition of the mission profile. Finally, several solutions were offered to protect aircraft during peace-keeping operations, i.e. an active self protection laser system against optical seeker head missiles.

FUTURE MILITARY ELECTRONIC WARFARE: WHERE WILL MODERN SIGNAL PROCESSING TAKE US?

Hill, Peter C. J., Cranfield Univ., UK; Saull, Ray C., Cranfield Univ., UK; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 10p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

Military electronic warfare (EW) is well recognized as a facilitating force multiplier in deciding the outcome of a conflict situation. Its operation depends very largely now on smart electronic signal processing. Modern developments in the fields of digital signal processing (DSP) algorithms, devices and systems and also in processing optical signals have been fast and a number of novel paradigms have emerged which will possibly have important repercussions in the EW arena. Selected cases are described together with research examples to show the progress and applicability of the new techniques. The main purpose of the paper is to focus on those hot signal processing developments which the EW community should be encouraged to monitor very closely.

THE IONOSPHERIC FACTOR: EFFECTS AND MITIGATION IN RF NAVIGATION, SURVEILLANCE AND COMMUNICATION

Bishop, Gregory J., Phillips Lab., USA; Mazzella, Andrew J., Northwest Research Associates, Inc., USA; Holland, Elizabeth A., Northwest Research Associates, Inc., USA; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 12p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The ionosphere is a factor in all RF systems that involve links between ground/air and space at or above 100 km altitude, and frequencies up to at least 4 GHz. Ionospheric scintillation can cause message errors in satellite communication links and reduced availability of satellites for GPS navigation. Ionospheric range errors can result in loss of accuracy or resolution in surveillance from space, or ground-based surveillance of space objects. The determination of whether the ionosphere will generate significant system degradation involves both environmental and system parameters. Environmental

parameters include: earth-space weather, time of day, season, time of the solar activity cycle, and region of operation. System parameters include: frequency, noise thresholds, and performance requirements such as accuracy, resolution, or data rate. Mitigation, if possible, must be adapted to the function and specific mission of the aerospace system. Two-frequency GPS navigation incorporates ionospheric measurement for range error mitigation. However, single-frequency GPS must depend on statistical models or adjunct differential techniques. Ionospheric scintillation, through loss of lock, or reduced signal margins, can reduce availability of satellites for maintaining GPS navigation integrity. GPS navigation systems can be designed to monitor signal quality and employ adjunct inertial systems over intervals when GPS availability is compromised. In communication, for some systems, special equipment and signal formats can reduce message errors. Local measurement-warning systems can also be used to monitor onset and location of ionospheric disturbances, and identify satellite links that remain clear. When linked to a scintillation model, such warning systems can provide regional capability to identify 'windows' for good operation of both surveillance and communication. Similarly, measuring systems that monitor ionospheric range error may be linked to region-adapted ionospheric models for surveillance correction. For systems with a wider mission, corrections outside the reach of a local monitor are required. These may be obtained from global networks of ionospheric sensors providing real-time input to global ionosphere and space weather models.

ADAPTIVE INTERFERENCE CANCELLATION AS A MEANS OF COPING WITH THE COMPLEXITY OF THE TARGET ARRAY AND THE PLATFORM ENVIRONMENT IN MODERN AND FUTURE COMMUNICATIONS ELECTRONIC WARFARE SYSTEMS

Horner, R., Siemens-Plessey Systems, UK; Thwaites, D. R., Siemens-Plessey Systems, UK; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 10p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The basic principle of adaptive interference cancellation is very simple, it is the removal of an unwanted interfering signal by algebraically adding a replica of the unwanted component which has precisely the same amplitude a opposite phase. This paper introduces the techniques of adaptive interference cancellation and describes a practical solution fielded with a major tactical system.

PREDICTION OF ANTENNA TO ANTENNA COUPLING BY USE OF A COMPUTER PROGRAM, BASED ON THE METHOD OF MOMENTS

Klook, Th., MAZ Hamburg G.m.b.H., Germany; Gonschorek, K.-H., Technische Univ., Germany; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 8p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

On complex systems like vessels, vehicles, planes and rockets often there are used closely spaced antennas. When planning the electromagnetic compatibility of such systems the question for possible interactions between transmitting and/or receiving equipment is a major problem. It has to be clarified how critical the coupling between closely spaced antennas will be, including the question of how the antenna pattern will be influenced. The simultaneous operation of two antennas is a very serious problem if the difference of the operation frequencies is very small. The coupling of power from one transmitter to the other (active influence) may produce malfunctions or damage the output stages. The possible detuning of the neighboring antenna (passive influence) is a further problem to be paid attention to. With the help of efficient software it is possible to carry out an effective planning of the electromagnetic compatibility of such kind of systems and to support the selection of suitable antenna locations.

The computation of different cases of influences will be described, with the help of the computer program CONCEPT, which is based on the method of moments (MoM).

MODELLING OF GUIDED MISSILES AND NUMERICAL SIMULATION OF THEIR INTERACTION WITH RF WAVES

Nitsch, Juergen, Wehrwissenschaftliches Inst. fuer Schutztechnologien - ABC-Schutz, Germany; Vogel, Hans-Joachim, Wehrwissenschaftliches Inst. fuer Schutztechnologien - ABC-Schutz, Germany; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 10p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

RF coupling into guided missiles is described on the basis of rough analytical estimates and of the application of the numerical MoM code CONCEPT. Coupling is maximized by resonant excitation in the external and internal resonance region of the missile and mainly takes place via slots in the surface of the missile and via the fins and stabilizers which act as antennas. In the senses of norms (infinity-(peak) and 2-norm (i.e. - square root of energy)) a damped sinusoidal waveform in general produces a response which is much larger than that due to a decaying exponential waveform.

EXPERIMENTAL HPM SUSCEPTIBILITY, EXPLOITATION OF SMART MUNITIONS

Bohl, J., Diehl G.m.b.H. und Co., Germany; Kaiser, A., Wehrwissenschaftliches Inst. fuer Schutztechnologien - ABC-Schutz, Germany; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 16p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Direct experimental exploitation and investigation of smart munitions are necessary to determine and analyze the coupling mechanisms from an outside electromagnetic field to the inside of the smart munitions where it can interact with the electronical guidance and control components as well as with the wiring. This interaction can lead to upsets on critical signals or/and to resonances on the signals. Numerical and analytical investigations are conducted prior to the experimental irradiation tests. For first approaches, direct injections of currents (normalized to the outer electric field) at the potential coupling paths (apertures and antennas) are applied to measure the resonances transferred to the inside of the munition. These test results are used as a basis for experimental exploitations at the live system with a defined simulated flight condition exposed to an electromagnetic

field. The important point here is that not all coupled resonances cause a reaction/degradation in the guidance and control loops of the complex systems.

TURBULENCE IN THE UPPER ATMOSPHERE: EFFECTS ON SYSTEMS

Basu, Santimay, Phillips Lab., USA; Bishop, Gregory J., Phillips Lab., USA; Larson, John, Space Command, USA; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 10p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The F-region of the ionosphere typically above 150 km at times becomes turbulent and develops small scale (less than 1 km) irregularities of electron density. These irregularities scatter radio waves from satellites in the VHF and UHF range and generate amplitude and phase scintillation. The magnitude of scintillation decreases with an increase of frequency but may be of concern at frequencies as high as 10 GHz. Scintillations are pronounced at equatorial and polar latitudes. The most severe scintillation is recorded over two belts, a few degrees wide at approximately 15 deg north and 15 deg south of the magnetic equator. The stations at Ascension Island, Diego Garcia, Hong Kong and Taiwan are located in this region where satellite communication links at 1.5 GHz may suffer 20 dB fades after sunset during the solar maximum period. The transmissions of GPS satellites at 1.228 GHz and 1.575 GHz are thus vulnerable. Scintillations cause message errors, cycle slips and loss of phase lock in satellite communication and navigation systems. In this paper, we first provide a summary of the climatology of scintillation with emphasis on the effects of scintillation on space systems. While the climatology of scintillation is fairly well established, the specification and forecasting of scintillation on a daily basis remains a challenging problem in view of the extreme day-to-day variability of scintillation, which is unfortunately most pronounced in the severely disturbed equatorial region. Attention is focused on this shortfall in the context of the recently formulated U.S. National Space Weather Program (NSWP) requiring the nowcasting and forecasting of the conditions on the sun, and in the solar wind, magnetosphere, ionosphere and thermosphere.

Accuracy of the electromagnetic cross sections of spheroidal particles computed using the discrete dipole approximation and the extended boundary condition method are checked in the high and low frequency limits and in the limit where the shape becomes spherical. We compute electromagnetic cross sections and intensity scattering matrix elements of spheroids with aspect ratios (major to minor axis ratios) up to four averaged over random orientations for a range of sizes where the major and minor axes are much greater than the wavelength and much less than the wave length. Complex refractive indices typical of dielectric material in the visible and infrared spectral regions have been chosen. Accuracy is judged based on comparisons with Mie theory calculations in the limit when aspect ratio approaches unity, with the Rayleigh spheroid theory in the limit when both size parameter and phase shifts are small, with the geometric optics theory in the limit when both size parameter and phase shifts are large, and finally in the anomalous diffraction theory in the limit of large size parameter and

complex refractive index near unity. In addition we use constraint inequalities involving the intensity scattering matrix elements to check the validity of randomly oriented spheroid calculations.

ENVIRONMENT MODELS AND THREAT SIMULATORS: HIGH QUALITY AND LOWER COST VALIDATION OF EW SYSTEMS

Pywell, M., British Aerospace Defence Ltd., UK; Stubley, N., British Aerospace Defence Ltd., UK; Environmental Factors in Electronic Warfare Related to Aerospace Systems; Jan. 1996; 12p; In English; See also 19960022241; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

Recent conflicts such as the Falklands campaign, Gulf conflict and Bosnia have amply demonstrated the importance of EW to Mission Effectiveness and crew. Survivability. In addition to this, since world-wide defence budgets are still reducing overall, the key driver for most Customers is Affordability, to a major aircraft prime contractor such as BAe Defence, these Customer requirements mean addressing a number of issues related to establishing the minimum necessary aircraft EW suite to satisfy those requirements. A key issue in this determination is a precise definition of the radar, RF and Electro-Optic (EO) electromagnetic environment that the aircraft must operate correctly in. This paper addresses this aspect and the tools and techniques necessary to produce aircraft EW systems that not only conform to specification, i.e. have no defects, but also have adequate performance, i.e. are 'fit for purpose'. It concentrates on the RF environment (modelling and threat simulators) as relevant to the testing of ESM/RWR/ELINT and ECM systems, although the principles are equally applicable to the EO, i.e. Infra-Red (IR) and Ultra-Violet (UV) regimes, and this is also discussed. It outlines EW System specification, describes EW environment modelling and its role in the design and validation process, covers EW Test and Evaluation (T&E) improvements, identifies shortfalls in current modelling capabilities, and gives major thrusts aimed at improving the EW development process. It addresses the issues above in the light of BAe Defence, Military Aircraft Division's experience in the field of both RF scenario modelling in support of a number of aircraft projects and planned ESM-ECM development work using scenario and equipment modelling, two world-class RF threat simulators, state-of-the-art ECM response measurement equipment and EW data analysis tools. It develops the argument that one of the main contributors to previous/current poor press on EW systems is believed to be the lack of adequate EW scenario definition at equipment/aircraft contract signature and that such definition should appear in specifications along side electromagnetic compatibility and other environmental issues.

MULTIFUNCTION MILLIMETRE WAVE RADAR FOR FUTURE MILITARY NAVIGATION

Roschmann, H. J., Daimler-Benz Aerospace A.G., Germany; Tospann, F. J., Daimler-Benz Aerospace A.G., Germany; Jun. 1996; 10p; In English; See also 19960053042; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

In future military transport aircraft or helicopters, the crew must be assisted under bad weather conditions to solve specific operational problems such as runway detection, landing, low level flight, ground mapping, and ground movement. Some of these applications can also be applied to unmanned aircraft. To provide these new functions, and enhanced vision system (EVS) is proposed. System and functional requirements for a millimeter wave radar proposed for the EVS are discussed in this paper.

A ground attack mission requires, in general, several target acquisition stages for the purpose of navigation (in order to calculate the aircraft position) or attack (in order to designate the target to be processed). Forward point radar is one technique that can be used for these acquisitions. Localization of a target can be achieved from the synthetic aperture radar (SAR) cards which are acquired during a mission by the radar. The localization procedure used can be manual (pilot designated on the card) or automatic (system proposed solution). This paper presents the principle methods employed to achieve this function as well as the main lines adhered to by Thomson-CSF.

Despite today's advantageous technological infrastructure, the amount of messages to and from various departments of the modern armed forces, have multiplied by such a factor, that they threaten to fill up the capacity of the existing communication systems. A more serious concern is the number of people required to execute or take some action on them. An intelligent information collection system should be able to manage with the coordinated employment of various types of sensors as well as with other information sources and to deal in real time with the collected data in order to provide the users at each level with secure, detailed and reliable information. The information should cover all aspects and factors concerning the development of the battle, i.e. from the enemy forces to the atmospheric conditions. Furthermore, one of the most important operational requirements is that the correlation, processing and distribution of data and information should concern all the interested centers and command posts wherever they operate. An intelligent information collection system should provide a global picture of the battlefield in real-time to allow the performance of the command and control functions. There is a clear requirement for computer-based data fusion aids to assist the officer in understanding what is happening. Underlying the whole data fusion process is the necessity of the human-computer interaction. Beyond the man-machine interface, interfacing with the inference system must be

possible. The incoming information that requires processing and its corresponding systems should be designed to operate in a very dense and complex EM environment in order to perform automatic enemy radar detection, analysis, identification, and very accurate localization. The incorporation of one or more expert systems is a key element in this processing. A distribution information system should comprise personnel, equipment, facilities and communications to provide authorities at all levels with adequate data to plan, direct, coordinate and control conventional air operations. The command and control activities supported by a distribution information system, for which the information exchange is essential, are: force management, command and control resource management, airspace management, surveillance, air mission control, and air traffic control.

AN ANALYTIC RAY TRACING MODEL FOR HF IONOSPHERIC PROPAGATION

Norman, Robert J., Defence Research Agency, UK; Platt, Ian G., Defence Research Agency, UK; Cannon, Paul S., Defence Research Agency, UK; Apr. 1996; 10p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The analytic ray tracing model described here is a near real-time ionospheric model which includes an approximation to the ionospheric profile which allows the inclusion of horizontal gradients. The results in this paper are encouraging, especially when we compare the propagation results when using the analytic ray tracing model with the numerical ray tracing, which traces through the synthesized ionospheric profile produced using the FAIM model. The percentage difference in the resultant ground range between the numerical ray tracing and the analytic ray tracing model described here is only 2.9%. Even less difference would be observed using smaller steps in grid size and using more grid layers. This will be investigated in a later paper. The analytic ray tracing model produces a fast approximation to the entire propagation footprint. In fact the analytic ray tracing technique described here together with the tilting method is more than 10 times faster than the numerical ray tracing package. Higher resolution regions of the footprint will still need to rely on, the slower, numerical ray tracing techniques. Thus, it is more than likely, in any particular application, that a propagation footprint may require a combination of both the analytic ray tracing model and numerical ray tracing techniques.

AN IMPROVED MODEL OF IONOSPHERIC ABSORPTION AT HF HIGH LATITUDE PATHS

Jodalén, V., Norwegian Defence Research Establishment, Norway; Thrane, E. V., Norwegian Defence Research Establishment, Norway; Apr. 1996; 12p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The performance of current HF prediction programs at high latitudes is often poor due to a lack of observations at these latitudes, but also because of incomplete understanding of the complex processes occurring in the ionosphere. Earlier work have shown that the prediction of signal strength and propagation using IONCAP/ICEPAC is too optimistic at high latitudes. This work introduces into ICEPAC a new model of electron densities in the high latitude D-region developed by Friedrich and Torkar, 1983. The model uses a statistical analysis to relate electron density profiles (60-120 km) to time of day and measured riometer absorption. We suggest that ionospheric loss on oblique incidence skywave paths be calculated in ICEPAC by integrating through the model using the Appleton-Hartree equation. Further we implement mode availability as an independent statistical factor to be multiplied with the probability of achieving a certain signal to-noise ratio. The new predictions are compared with HF measurements on a high-latitude path within Norway. The modifications have

improved the agreement between data and predictions, particularly for disturbed geomagnetic conditions. For example, the observed diurnal variation of absorption is now reflected in the predictions.

PASSIVE HF PROPAGATION EVALUATION TECHNIQUE

Soicher, Haim, Army Communications-Electronics Command, USA; Houminer, Zvi, Technion - Israel Inst. of Tech., Israel; Apr. 1996; 8p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Reliable communications among mobile as well as fixed HF skywave nodes along short, medium and long-range paths require propagation assessment. Such assessment could be facilitated with the monitoring of ionospheric characteristics by continuously available passive means i.e., measurement of the Total Electron Content (TEC) using satellite-emitted signals without a need for burdening the electromagnetic spectrum. With the availability of the ubiquitous Global Positioning System (GPS) to provide instantaneous time-delay, or equivalently TEC, values when needed, an assessment of HF propagation conditions may be available on a near-real-time basis. Both TEC and the peak electron density of the ionosphere, which determines the ordinary upper frequency limit ($f_{(sub\ 0)F}(exp\ 2)$) for HF skywave vertical propagation, vary strongly with solar and geomagnetic parameters. Their ratio, the equivalent slab thickness, may vary to a much lesser degree and as such may be modeled with greater accuracy. A slab thickness model combined with real-time TEC measurement anywhere on the globe may thus yield an improved HF parameter prediction algorithm. To test the efficacy of the hypothesis, one has to ascertain the correlation between the TEC daily variability about the monthly mean and the $f_{(sub\ 0)F}(exp\ 2)$ variability. To determine such correlation a study was conducted using Faraday TEC data as well as GPS generated TEC data collected in Israel and comparing it to $f_{(sub\ 0)F}(exp\ 2)$ measurements near the appropriate subionospheric location in Cyprus. The analysis shows that for large percentages of the time very good correlation exists between TEC and $f_{(sub\ 0)F}(exp\ 2)$ short-term variations. The correlation coefficient varies between 0.7 or better during winter and summer months to about 0.5 - 0.6 during equinox months. A study of the diurnal dependence of the correlation indicates that a better correlation exists during daytime than nighttime. There was no indication that the coefficient is dependent on geomagnetic activity during the period of this study.

This paper discusses ongoing work by AT&T Bell Laboratories, Pennsylvania State University, Polytechnic University and Virginia Polytechnic University in developing site specific urban propagation computer models. Both two and three dimensional ray tracing algorithms have been developed by the different organizations and applied in the Rosslyn VA area at 900 and 1900 MHz. After the models have predicted the propagation loss from specific transmitter sites to receiver locations, measurements have been taken to determine the actual values. This paper presents some comparisons of the different models and measurements. Where the computer models have worked well, they are typically within about 7 dB of measurements. In some areas of Rosslyn there are known problems with the building data base where predictions differ from measurements, however work is continuing to improve the models in other problem areas. This will be accomplished by comparing the different models to one another and the measurements and then refining the models.

New electromagnetic propagation code suitable for use in complex urban environments has recently been developed and demonstrated by a collaborative group of researchers. These methods use a combination of two- or three-dimensional ray tracing reflection, diffraction, diffuse scattering, and transmission rather than electromagnetic field theory to solve the path loss problem. Although still under development, initial versions of the code predict propagation in complex urban environments with useful accuracy. Looking beyond this research, this paper addresses potential military use of site-specific propagation models and simulations, focussing on its use in distributed interactive simulations

A MODEL FOR ESTIMATING ELECTROMAGNETIC WAVE ATTENUATION IN A FOREST (EWAFF) ENVIRONMENT

Welch, Conrad, Computer Sciences Corp., USA; Lemak, Catherine, Computer Sciences Corp., USA; Corington, Lee, Army Electronic Proving Ground, USA; Apr. 1996; 6p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

For decades, communicators have been concerned with Radio Frequency (RF) propagation path loss through foliage. This paper describes the development and implementation of the Electromagnetic Wave Attenuation in a Forest (EWAFF) propagation path loss model, which uses conventional inputs to estimate plausible foliage losses. The EWAFF is an elementary, heuristically based foliage propagation path loss model which represents a forest as a dissipative dielectric slab lying in a more lossy half-space representative of the ground. Modeling the foliage by a dielectric slab will provide an estimate of foliage path loss in excess of free space (EPL) expected in situations where meager information is available regarding the wood density and other electrical parameters of the forest. The EWAFF model uses empirical foliage path loss information as a basis and is therefore closely coupled to actual path losses encountered in real-world situations. The EWAFF model is not a rigorous attempt to solve the electromagnetic wave equations at the boundaries of the different representative dielectric slabs. Rather, EWAFF is essentially a family of curve-fitting algorithms based on previously measured data for sparse and dense forests in the USA and Germany, as well as very dense forests in India, where the mean annual rainfall is about 3000 millimeters. The EWAFF model includes several features: the effects of

antennas within the forest, outside the forest, and above the forest; wave polarization; forest density; canopy, trunk, and undergrowth losses; antenna beamwidth; wet foliage; lush foliage; and other physical/forest conditions. It is presently resident on a Sun SPARC network and provides a good estimator for EPL due to foliage anywhere in the world.

ATMOSPHERIC PATH LOSS AND SCINTILLATIONS AFFECTING COMMUNICATIONS IN THE EHF FREQUENCY RANGE

Fuchs, H. H., Forschungsinstitut fuer Hochfrequenzphysik, Germany; Makaruschka, R., Forschungsinstitut fuer Hochfrequenzphysik, Germany; Digital Communications Systems: Propagation Effects, Technical Solutions, Systems Design; Apr. 1996; 8p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

With the introduction of millimeter wave bands for satellite communications attenuation effects in the troposphere become adversely important. To investigate these propagation phenomena especially due to clouds an experiment has been set up on a 9420 m slant line-of-sight path in the German Alps between Garmisch and the top of the Zugspitze. The measurements were made at the frequencies of 35 GHz and 94 GHz. Hourly observations of the German Weather Service at both locations gave estimates of the height, thickness and type of the clouds. The measured data were evaluated in a statistical manner. Comparing the results with calculations based on standard drop size distributions for various cloud types an increase in the attenuation levels was observed. This difference can be explained by the presence of super-large drops in clouds as recently measured and reported. Though their contribution to the total liquid water content is small, the effect on the attenuation is enhanced. A second propagation experiment was performed on a 1340 m long, terrestrial line-of-sight path to evaluate the scintillation effects at 94 GHz. It was found that the power spectrum of the measured log-amplitudes follows the -8/3 slope of the theoretical pattern based on Kolmogorov's refractive index spectrum. The refractive index structure constant $C_n(\text{sub } n)(\text{exp } 2)$ calculated from variances of the measured log amplitude agree well with those deduced from meteorological measurements after applying a semiempirical relation for height scaling the various sensors. This result establishes the applicability of theoretical relations for scintillation effects at mm-waves due to Tatarski and Kolmogorov.

A model for the calculation of the absorption and dispersion spectra of the most important and millimetre-wave active atmospheric gases for arbitrary atmospheric geometries is presented. The model adopts a line-by-line summation technique to characterize the resultant resonant absorption and dispersion spectra of various trace constituents and major contributors H₂O and O₂. A spherically layered atmosphere is assumed with each layer taken to be in Local Thermodynamic Equilibrium (LTE) with exponential profiles of density and pressure between layer boundaries. The relative air mass integral and the lineshape functions are also appropriately evaluated according to atmospheric conditions. Various model atmospheres may be selected or specified by the user.

The military use of space for communications has seen dramatic changes since its first use in the 1960's. This paper presents some of the advances made, explores some of the current technical trends and proposes some key areas which need to be addressed in the future. The use of 3-axis stabilized rather than spin stabilized satellites has enabled a significant increase in the DC power which can be generated using large solar arrays and has provided the platform necessary to mount sophisticated electronics and large, complex antenna systems. The advantages of satellite communication over terrestrial systems in terms of coverage, availability and ruggedness are now widely accepted. The modern demand for highly flexible and rapid force deployment by NATO and Allied powers has further strengthened the case for satellite communications. Survivable communications is a vital component in the C(Exp 3) systems necessary for efficient military deployments during stress. The Gulf Conflict demonstrated for the first time the full potential of space systems in military operations. Satellite communications in particular played an essential role in support of all operations both land based and shipborne. Satellite communications continue to provide vital support to NATO activities in Bosnia. At a time when budget pressures are leading to critical reviews of expenditures amongst allied nations the need for the retention of a highly resilient space resource remains paramount. The end of the Cold War has not fundamentally reduced the potential threats to the Allied nations. Satellites remain a key resource to maintain both national security and for humanitarian and peace keeping roles worldwide.

EARTH-SPACE LINKS AND FADE-DURATION STATISTICS

Davarian, Faramaz, Jet Propulsion Lab., California Inst. of Tech., USA; Apr. 1996; 6p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

In recent years, fade-duration statistics have been the subject of several experimental investigations. A good knowledge of the fade-duration distribution is important for the assessment of a satellite communication system's channel dynamics: What is a typical link outage duration? How often do link outages exceeding a given duration occur? Unfortunately there is yet no model that can universally answer the above questions. The available field measurements mainly come from temperate climatic zones and only from a few sites. Furthermore, the available statistics are also limited in the choice of frequency and path elevation angle. Yet, much can be learned from the available information. For example, we now know that the fade-duration distribution is approximately lognormal. Under certain conditions, we can even determine the median and other percentiles of the distribution. This paper reviews the available data obtained by several experimenters in different parts of the world. Areas of emphasis are mobile and fixed satellite links. Fades in mobile links are due to road-side-tree shadowing, whereas fades in fixed links are due to rain attenuation.

OPTOGEOMETRICAL CHARACTERISATION OF ERBIUM DOPED FIBRES

Ravet, F., Mons Univ., Belgium; Heens, B., Mons Univ., Belgium; Megret, P., Mons Univ., Belgium; Blondel, M., Mons Univ., Belgium; Jaunart, E., Belgacom, Belgium; Apr. 1996; 6p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The reliability of the new photonic network components is becoming one of the challenges of the present years. The Erbium Doped Fibre (EDF) can be considered as one of these devices contributing to the optical communication systems upgrading. These are the reasons why easy-to-reach EDF optogeometrical properties seem to be more and more important. Within this context, an experimental set-

up has been developed permitting the measurements of these properties (mode field diameter, core diameter, refractive index profile, Numerical Aperture...). Our set-up is based on the Transmitted Near Field Technique (TNFT), combined with an infra red camera detecting the near field intensity magnified by an infra red aspherical lens. Such a method has been successfully demonstrated in the past for the optogeometrical characterization of single mode fibres. The combination of the TNFT with the infra red camera opens the possibility of yielding very quick measurements. The importance of the camera lies in the two dimensional intensity detection: such a device records and instantaneously displays the intensity distribution. The NFI pattern is thus easy to get. The mode field diameter has been determined from the Near Field Intensity (NFI) pattern and we then calculated the refractive index profile difference. Finally, we determined the fibre core radius and numerical aperture. We then compared them with the Equivalent Step Index parameters we have calculated. We carried out all these measurements at 1310 nm and 1550 nm. So we have direct informations on the optogeometrical parameters in the second and third windows.

The increased sophistication of the modulation schemes employed by High Frequency (HF) data modems has necessitated a better understanding of the effects of the ionosphere on propagated signals. This paper describes an HF pulse compression radio sounder, that is being used to characterize high latitude HF paths. Results from operations of the sounder in Scandinavia are also presented.

The auroral zone ionosphere forms a highly dynamic and disturbed medium which can severely degrade the performance of HF radio links when the signals propagate through these regions. In order to investigate this effect, a series of experiments have been undertaken over a variety of high latitude paths for which the Doppler spreading imposed on the signal by the ionospheric reflection processes and FSK data signalling error rates and distributions were measured. The Doppler spreads observed over two of these high latitude propagation paths are examined in this paper for two experimental campaigns, one conducted during the summer months and the other during winter months. One of these paths was contained entirely within the polar cap and another of the paths was sometimes entirely within the polar cap and at other times crossed the auroral oval. Times of increased Doppler spreading on the second path were found to be well correlated with periods for which one of the ionospheric reflection points was within, or close to, the boundaries of the statistical position of the auroral oval. The bit error rate of the FSK signals was not influenced by the high level of Doppler spreading observed on the path crossing the auroral oval. However, the distribution of bit errors was markedly affected by changes in the Doppler spreads. At times of high Doppler spreading, the length of the error bursts was significantly less than for the cases where the Doppler spreading was small.

Here we compare wave forms that are both capable of coherent demodulation by virtue of the presence of reference symbols. First, we attempt to compare the intrinsic performance parameters of wave forms in the case of CCIR type channel model (several trajectories for a few milliseconds affected by independent Rayleigh fadings). In this type of channel, the parallel wave form should behave as in the presence of a flat fading. The form of a series wave should benefit from the diversity effect related to independence of the fadings, and therefore should present greater error rate curves, the intrinsic performance parameters in presence of a single trajectory being identical.

CHANNEL EVALUATION FROM PREDICTED ZERO-CROSSING ANALYSIS

Piggin, P. W., Leeds Univ., UK; Gallagher, M., Leeds Univ., UK; Apr. 1996; 8p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper presents an investigation into Real-time Channel Evaluation (RTCE) from predicted zero-crossing analysis of: (1) A pilot-tone, and (2) Frequency Shift Keying (FSK) modem tones within a HF (High Frequency) radio system. This work extends the Initial investigations from the early 1970s which used an analogue implementation analyzing phase perturbation by time-differential phase comparisons of a low-level pilot-tone inserted in-band. The results to be presented in this paper compare theoretical analysis and measured results in Gaussian and flat fading conditions, and hence identify the close relationship between phase threshold, zero-crossing error rate and SNR (Signal-to-Noise Ratio). It will conclude with recommendations for extending the applicability of the technique to FSK (Frequency Shift Keying) systems and outline methods for incorporation into frequency management systems for various different radio systems operating in the HF, VHF and UHF bands.

For military short wave communication systems two waveforms have been standardized-STANAG 4285 and MIL-STD-188-110A. For these waveforms modems are available on the market. In this paper design rules that have led to these waveforms are recalled briefly and compared with modern signal design techniques. Knowing the shortcomings of standardized waveforms, the incorporated redundancy has been intensively used for advanced modem design. These new technologies have proved great performance enhancements in Daimler-Benz Aerospace new HF modem Echotel ETM1810/M for STANAG 4285 and MIL-STD-188-110A waveforms. Improvements have been achieved mainly in tolerance to Doppler and Delay Spread. Results are presented in this paper.

The National Telecommunication Research Center (CNET) has a connection analyzer available that allows one to measure, on the one hand, the main propagation parameters of the ionosphere channel and, on the other hand, the spectral occupancy rate of this channel. In the article, a method is proposed that allows one to discriminate and to simply quantify this spectral occupancy rate in order to serve as the basis for subsequent studies of the search for clear channels in an operational context.

The decametric band spectrum reveals a very large number of interferences whose distribution will depend on users and the condition of the ionosphere. A modeling of the interferences can be carried out by observing the received levels over the entire range. It has been possible to carry out such a classification with respect to the field level captured at one point of the ground surface.

This paper deals with the problem of coherence bandwidth of troposcatter radio links in the VHF frequency range. Partial reflections (specular and diffuse) on tropospheric sheets (feuillets) is the propagation mechanism considered. A propagation model (ASTRAL), which considers the appearance of such rough surface in the common volume, is then used. For a given VHF link, a numerical integration allows the determination of the received power. In this paper, we show that modelling the troposcatter propagation in such a way allows the evaluation of the coherence bandwidth of the channel by calculating the power delay profile. Some numerical examples are given and discussed.

COMMUNICATIONS AND THE GLOBAL POSITIONING SYSTEM

Aarons, Jules, Boston Univ., USA; Mendillo, Michael, Boston Univ., USA; Yantosca, Robert, Boston Univ., USA; Apr. 1996; 14p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

Position data obtained by use of the Global Positioning System (GPS) form basic components in a myriad of military and commercial systems. These range from navigating harbors and oceans to determining aircraft, rocket, and satellite positions. The users of GPS envisage automatic and routine communication of results of position

data for control and location of resources. Propagation studies to support these needs require the evaluation of problems of finding the position of ground, naval and airborne units and then communicating the data. The area addressed by this paper outline the problems of global fading of signals for both the GPS system and the satellite communication systems at 250 MHz which are used to communicate and integrate results. For GPS frequencies (1.2 GHz and 1.6 GHz) difficulties will be encountered in the auroral region during magnetic storms during all phases of the sunspot cycle. The equatorial and polar regions will become important by the end of the millenium when the sun will exhibit maximum activity. The data base for evaluating the effects of the ionosphere on gigahertz scintillation is small but will be outlined in this paper. The effects of F layer ionospheric irregularities on communication links at 250 MHz are considerable even during the current solar minimum. The data base for ionospheric effects on satellite communication systems at 250 MHz is large and will be only briefly outlined; much of the material is in various publications. It should be noted that transmissions for the IRIIDIUM series of satellites are in the same frequency band as the GPS transmissions and will be affected by F layer scattering.

The search for sequences that offer good periodic correlation functions is a subject on which a number of studies have been carried out. It has been demonstrated that with the exception of a trivial case, there are no binary sequences with perfect correlation. Some binary sequences with almost perfect correlation, the WG (Wolfmann-Goutelard) sequences, were proposed in 1992. These sequences are such that outside the central peak of correlation and a point located in the middle of the period of the correlation function, this function is always null. The perfect correlation sequences can therefore exist in the Q-airy sequences only. The GQ (Goutelard Q-airy) sequences are sequences that offer perfect correlation functions and which can be broken down into orthogonal subsequences with almost perfect correlation.

Analytic signal processing has gained wide acceptance in the electronics community and it is important to define the transform family which allows regular analytic samples of a signal to be calculated from its real sampling. This paper is composed of three main parts. The first part shows that band limited continuous signals are well approximated by trigonometric polynomials whose frequencies lie within a frequency band of the same width, and that we may thus represent these signals by analytic samples. The second part is devoted to the derivation of an explicit formula for the weighting coefficients used to calculate the two cartesian coordinates of the complex samples. The third part reviews some properties of this transform from the signal processing standpoint.

The Research Institute for Human Engineering (FAT) has been working in the field of land telerobot systems for the last six years. The main goal of current research work is the optimization of remote control and supervision of semiautomatic vehicles from a single control station for various missions. The research work done on a particular aspect of robot deployment in a driving task will be described in this paper. Robots are likely to be positioned at particular locations or to be moving in a terrain overlooking areas of military interest, such as likely enemy positions, contested areas, or supply lines. During the moving operation the robot is autonomous and ready to detect obstacles in a selected part of the landscape in front of it. After the robot is programmed with its mission there is no need for further radio communication until an obstacle is sensed which it cannot interpret because the automatic recognition system cannot recognize all threatening object situations for the driving task. 'Upon request', the vehicle requires help and support from humans. In this case the human acts

as a remote controller and supervisor. In a remote control station he receives still pictures or picture sequences obtained from the vehicle over a communication channel.

ANALYSIS OF PROPAGATION EFFECTS AND NON-LINEAR DISTORTIONS ON DIGITAL MODULATION SCHEMES

Metzger, Kurt, Telekom Forschungszentrum, Germany; Valentin, Rolf, Telekom Forschungszentrum, Germany; Apr. 1996; 8p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The paper deals with the analysis of digital transmission systems which are corrupted by thermal noise, linear channel dispersion and nonlinear distortions which are caused by the transmit amplifier. The central part of this analysis is a recursion model for the calculation of the probability density function (pdf) of Intersymbol Interference (ISI). The nonlinearity introduces statistical interdependencies between the interfering symbols and these dependencies are implicitly taken into account in a trellis-structured recursion rule. The procedure was applied to 4-level modulation schemes such as 4-QAM, offset 4-QAM and linearized GMSK. The results were verified by time consuming Monte-Carlo simulation and show, e.g., that the nonlinear characteristic of a high power amplifier (HPA) reduces in some cases the error probability caused by the linear dispersion. Surprisingly, the ISI due to the nonlinear amplifier is increased in the case of offset modulation.

INTEGRATED DATA AND CHANNEL ESTIMATION FOR SELECTIVE FADING CHANNELS

DAmbrosio, Luca, Aquila Univ., Italy; Marchesani, Rossano, Alcatel Espace, France; Ruggieri, Marina, Aquila Univ., Italy; Digital Communications Systems: Propagation Effects, Technical Solutions, Systems Design; Apr. 1996; 8p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Per-Survivor Processing is a general approach including in the survivors of the Viterbi Algorithm trellis the relative estimation of unknown parameters; this expensive method better approximates the optimum decoder in some conditions. The method is applied to the case of a typical HF channel and performance is evaluated. Some reduced complexity implementations are also evaluated and relative performances reported.

LINK LEVEL PROTOCOLS FOR RADIO CHANNELS

Yavuz, Davras, Shape Technical Center, Netherlands; Apr. 1996; 8p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Describing and/or modelling the characteristics of transmission channels is the most important aspect of performance estimation for most communication systems. Many analytic techniques for determining performance under well defined conditions such as additive Gaussian noise, Poisson impulsive noise, exist. However, some channels are too complex in terms of noise effects, interference and time variability to model with fidelity. The most outstanding example of this is the HF sky wave channel for which 'some good channel simulator performance' is required prior to fielding of a system. However, in general this is only a necessary but not sufficient condition for acceptable on-air performance. Link level or layer two protocols provide an excellent means to reduce the effects of such uncertainties. The basic approach is to use packetization (packet radio) to allow an automatic request for repeat (ARQ) process to continuously trade-off throughput with channel conditions. Many other facilities such as link establishment/maintenance and adaptive modem speed control can also be incorporated. With such an approach the source information (data,

message, fax, image and packet digital voice) will always be communicated to the destination with no errors but the transmission (or delivery) time will vary with channel conditions; the worse the channel the longer it will take to transmit the information. Packet radio techniques were originally developed by DARPA for networking and survivable multi-homing applications over terrestrial/fixed links. However, the link level applications over complex channels are now increasing significantly. This paper/presentation will present examples of link level protocol work that has been performed at SHAPE Technical Center. Specifically, link level ARQ protocols developed for HF sky wave and meteor burst communications will be covered. More recent work on a packet radio protocol for data communications over analog frequency hopping radio systems will also be described.

DEFINITION OF A COMMUNICATION SYSTEM USING THE TROPOSPHERIC CHANNEL

Vivier, G., Alcatel Espace, France; Brelivet, P., Alcatel Espace, France; Richard, J., Alcatel Espace, France; Sehier, P., Alcatel Espace, France; Apr. 1996; 8p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Many transmission channels, like the radio channel or the tropospheric channel, are frequency selective and time variable. Receivers designed for this type of transmission have to fight against intersymbol interference generated by the multiple paths and at the same time adapt to the time variations of the channel. Only with progress in digital technology, leading to the application of new concepts of advanced equalization and error correcting codes, will good quality, high bit rate transmission become achievable on this type of channel. This article covers high bit rate communications (of the order of 8 Mbit/s). The first part discusses the special features of the tropospheric channel and system aspects that must be considered when attempting a complete definition of a communication system on this channel. The second part describes two waveforms, associated with their respective receivers, designed to meet the requirements identified in the first part. The first, designed for a single-carrier modulation system, is based on an architecture combining equalization, decoding and deinterleaving. This method, introduced by R. Mehlman and H. Meyr, is called Combined Equalization and Decoding (CED) in the remainder of this article. The second is a single-carrier alternative known as Coded Orthogonal Frequency Division Multiplexing (COFDM), adopted for digital audio broadcasting (DAB), and envisaged for digital terrestrial TV broadcasting. In the second part, we attempt to compare these two methods in terms of Bit Error Rate (BER), obtained by simulations in conditions approximating a real link, and in terms of difficulty of implementation.

COMPARISON OF RLS ADAPTIVE ARRAY ALGORITHMS IN A STRONG MULTIPATH PROPAGATION ENVIRONMENT

Peeters, D., Katholieke Univ. te Leuven, Belgium; VanLil, E., Katholieke Univ. te Leuven, Belgium; Apr. 1996; 10p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Most of the algorithms for spatial multiplexing are tested under simple multipath conditions. In this paper a more complete and realistic model for the communication channel is described, taking into account local dispersion, Doppler-shift, multipath propagation and thermal noise. Based on this model, a program has been written to actually compute the effect of the complex environment on the signals. The numerical data for the multipath effect were taken from the GSM Recommendation 05.05 'Radio Transmission and Reception'. With the results of this propagation simulation program, algorithms of the RLS type are compared. It is found that the difference in performance between the S-RLS algorithm and the QR-RLS algorithm is negligible. Because of the limited length of the training-sequence, the number of coefficients to be determined must be kept low. Additional time-equal-

ization does not improve the reception substantially. Also, due to the Rayleigh fading, the amelioration of the reception at decreasing noise levels stagnates.

TESTING HF-MODEMS: DSP'S OPEN NEW POSSIBILITIES AND MAKE NEW DEMANDS ON REAL-TIME HF-SIMULATORS

VanderPerre, Liesbet, Katholieke Univ. te Leuven, Belgium; VandeCappelle, A., Katholieke Univ. te Leuven, Belgium; Apr. 1996; 10p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

A test set-up for HF-modems with a hardware implemented, mainly analogue simulator based on the Watterson model, has been built at the division ESAT-TELEMIC of the K.U.Leuven. It has shown to be a very useful tool to test narrowband HF-modems under stable channel conditions. In order to improve the transmission quality, more advanced HF-modems are being developed nowadays. The use of DSP's (Digital Signal Processing) has made it possible to provide large interleaving blocs, intelligent error correcting coding schemes, channel estimators, adaptive equalizers, etc... The qualities of such modems, that try to adapt to the present channel conditions, can only properly be tested on, provided they are subjected to varying channel conditions. The technological evolution that gave rise to these intelligent modems, has created the need for a simulator that can imitate a varying ionosphere. This is what is aimed using a digital signal processor for the realization of an HF-channel simulator. Besides the programming capabilities that are automatically present when using DSP's for channel simulation, other advantages come when working digitally. Making adjustments to a design becomes a very simple operation, and some simulation functions are easier to implement when working with digital technology. The design of this digital simulator is done using a digital signal processing design tool called Signal Processing Worksystem (SPW). The use of spread spectrum modulation techniques on the HF-channel, creates a new challenge for the developers of HF channel simulators. In the first place, because there is no wideband model for the HF channel available. Besides that, the realization of a real-time simulator that can handle signals with bandwidths up to 1 or 2 MHz, will be a complex task, both from a hardware and a software point of view.

A FLEXIBLY CONFIGURABLE STATISTICAL CHANNEL MODEL FOR MOBILE RADIO SYSTEMS WITH DIRECTIONAL DIVERSITY
Blanz, J. J., Kaiserslautern Univ., Germany; Jung, P., Kaiserslautern Univ., Germany; Baier, P. W., Kaiserslautern Univ., Germany; Apr. 1996; 12p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

A prerequisite for the performance analysis and optimization of future mobile radio systems by simulation is a realistic model of the mobile radio channel. Time variance and frequency selective fading as well as spatial radio spreading have to be considered in such a model to enable the validation of system concepts using directional diversity. In this paper, a flexibly configurable statistical channel model for mobile radio systems using directional diversity is presented. This channel model is based on the superposition of echoes which originate from different scattering objects. The parameters of this model can be easily adjusted to various propagation areas as e.g., rural, urban, microcellular, and picocellular environments. Therefore, the model which is the basis for a FORTRAN77 program is well suited to perform simulations, evaluations and comparisons of mobile radio systems. Simulation examples are given for typical mobile radio scenarios. The resulting time varying channel impulse responses for both omnidirectional as well as ideal non-overlapping sector antennas are compared.

The applicability of the presented channel model to simulations of mobile radio systems is demonstrated for a new mobile radio system concept with joint detection (JD) and directive base station antennas.

SITE-SPECIFIC RADIO PROPAGATION PREDICTION METHODS FOR URBAN ENVIRONMENTS

Luebbers, R., Pennsylvania State Univ., USA; Schuster, J., Pennsylvania State Univ., USA; Apr. 1996; 14p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

With high frequency portable communication systems becoming more common, the need for fast and accurate predictions of high frequency radio propagation in urban environments has rapidly increased. Until recently such predictions were usually based on empirical methods, especially if relatively large numbers of predictions were required. But advances in both computational methods and computer speeds now allow for fast, site-specific predictions of radio propagation even in complex urban areas. In this paper we are primarily concerned with narrow band signal attenuation, but the ray methods to be discussed are also applicable to determination of signal delay and delay spread. Various approaches being used for such predictions are discussed in this paper. The most popular current approaches involve some combination of shooting multiple rays and evaluating their amplitudes using diffraction theory. For this reason we will concentrate our paper on this approach. Basic considerations in the application of ray methods will be discussed, and some typical results are presented.

Meteor burst is a unique mode of communication which relies on the trails of ionization that are created when meteoric particles enter and burn up in the Earth's atmosphere. Due to the serendipitous nature of these events, these meteor burst channels are inherently intermittent but do possess characteristics which are attractive in military applications. Among these features are the potential for long-range communication (up to distances of 2000 km), low probability of jamming or intercept, and invulnerability to attack by either nuclear or conventional means.

EXPERIMENTAL DESCRIPTION AND MODELIZATIONS OF METEORIC CHANNELS DESCRIPTION EXPERIMENTALE ET MODELISATIONS DU CANAL METEORIQUE

Ravard, O., Rennes Univ., France; Sorais, D., Thomson-CSF, France; Digital Communications Systems: Propagation Effects, Technical Solutions, Systems Design; Apr. 1996; 10p; In French; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The meteoric channel can be described, over a given period of time, by the duty cycle and the mean waiting time. The objective of this paper is to give an analysis of the channels statistical parameters and to describe different kinds of channel modelling. The statistical analysis is based on experimental data. We show the effects of fading, observed on the received signal, on the channel parameters. We present different kinds of meteoric channel modelling which take account for underdense sporadic meteor trails. These modelling allow the consideration of the most important problems; the astronomical problem to evaluate the meteor distribution on the sky; the ionization problem to determine the electronic density created by the meteor; and the propagation problems. The performances of these modelling are evaluated.

BEAM FORMING TECHNIQUES IN METEOR SCATTER COMMUNICATIONS SYSTEMS

Akram, Ammad, Defence Research Agency, UK; Cannon, Paul S., Defence Research Agency, UK; Apr. 1996; 8p; In English, USA; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Experimental and modelling results from a program to improve the data throughput of meteor scatter communications systems are presented. The method of passive beam formation using a 4-element Butler matrix to improve the signal availability of meteor scatter communication systems is investigated. Butler matrix signal availability is compared with the performance of a single Yagi reference system using approximately 6.5 hours of data from a 720 km North-South temperate latitude link. The signal availability gain of the Butler matrix is found to range between 1.6-1.8 over the SNR threshold range 20-30 dB. At low SNR, the Butler matrix also compares favorably with a system employing adaptive beam formation driven by direction finding. The overhead time needed to continually direction find with the gain of a single antenna mitigates against the adaptive scheme at low SNR. For high SNR signals, however, the adaptive system outperforms the Butler matrix. A detailed computer model designed to predict the duty cycle of a general forward meteor scatter communications link has also been developed. The model incorporates effects such as major shower streams, a non-uniform radiant distribution and antenna polarization coupling, including Faraday rotation. A particularly useful aspect of the model is its capacity to predict the passage of hotspot regions across the sky. Experimental results are presented to validate the accuracy of these predictions. A computer controlled single high gain beam meteor scatter system is eventually envisaged.

More and more computations of coverage areas of a transmitter are now deterministic as opposed to the empirical or semi-empirical methods that don't give the precision nowadays needed. The deterministic methods mostly use direct, specular reflected and diffracted rays. It has been shown recently, that specially for indoor propagation, the diffuse reflection cannot be neglected. Diffuse reflection is caused by the roughness of the terrain and can occur outside the incidence plane. In a digital terrain model, triangles can be used to accurately describe the environment. Therefore the classical formulas for diffuse reflection have to be adapted to make the use of triangles possible. Some mathematical problems that arise, caused by the division of the rectangle in two triangles, with two different center points, are discussed in this paper. As diffuse reflection is caused by the roughness of the terrain, this is an important parameter. This roughness is, just as the specular reflection coefficient, determined by the sort of terrain that reflects. Research has still to be conducted on the determination of this parameter, as well as on the optimal distribution. Finally this model is used in a program for computing the coverage area optical. It is especially useful in cases where the digital terrain model has a resolution of a few Lambda's and when computer time is not unlimited.

INTRODUCTION TO RURAL AREAS TELECOMMUNICATIONS AND DEVELOPMENT OF A PILOT TERMINAL UNIT

Makri, Rodoula, National Technical Univ., Greece; Gargalakos, Michalis, National Technical Univ., Greece; Uzunoglu, Nikolaos K., National Technical Univ., Greece; Apr. 1996; 10p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Rural areas present special characteristics which must be taken under consideration when designing their telecommunication networks. These characteristics and their effects on systems design are examined in detail. The design of a pilot terminal unit in a block diagram form is presented with a brief explanation of its specifications and subunits. Various applications of this system concerning rural areas are viewed. Modern applications such as telemedicine and tele-

teaching can be realized with the use of this system. Military use is also a promising perspective of the system. Alternative solutions that could increase systems capacity and range are also examined.

COMMUNICATIONS AND SITUATION AWARENESS ON HOSTILE BORDERS

Kocher, R. W., Advanced Research Projects Agency, USA; Allen, J. G., Science Applications International Corp., USA; Digital Communications Systems: Propagation Effects, Technical Solutions, Systems Design; Apr. 1996; 12p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

In military operations, it is essential that commanders maintain an awareness of the location of subordinate units. The U.S. and other nations have deployed troops under United Nations' (UN) auspices to observe activity along potentially hostile borders. In these operations, there is always a danger that troops may inadvertently stray into a restricted area or cross a border. A system is needed to provide situation awareness by monitoring the position of soldiers (or the vehicles they are mounted in) and to warn when a soldier is entering a restricted area. Such warning should be provided to the soldier himself and also to higher echelons. If a higher echelon is aware of an emergency situation it may attempt to warn the soldier by independent means and also initiate the preparation of a reaction team.

COMMUNICATIONS REALISM WITH INTEGRATED TERRAIN-ENVIRONMENT-MULTIPATH MODEL

Sheth, Chandrahant, Army Communications-Electronics Command, USA; Barone, Salvatore, Army Communications-Electronics Command, USA; Lambert, Mark R., Maden Tech Consulting, Inc., USA; Kennedy, Lonnie R., Telos Corp., USA; Apr. 1996; 6p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Modeling and simulation (M&S) that assists the system developer or warfighter in defining, prototyping, testing and training should be executed with a high level of fidelity-this includes communications simulations. Current virtual, constructive, and systems performance simulations do not provide the dynamic irregularities at the lower link/physical layers that stress On-The-Move (OTM) communications, either assuming perfect communications or including statistical averages of error effects. The U.S. Army communications-Electronics Command Research, Development and Engineering Center (CECOM RDEC) has been developing models engineering 'communications realism.' Communications realism is a simulation feature through which a synthetic environment reflects the same communications problems that exist in a real environment. The purpose is to provide realistic tools for developing OTM communications systems that ensure reliable connectivity on the digitized battlefield. The Combined Arms Command and Control (CAC2) Advanced Technology demonstration (ATD) is a key program for supplying digital capabilities for the USA Army's concept of the digitized battlefield. The CAC2 system performance model (SPM) was developed under the CAC2 ATD as an economical means of evaluating proposed system designs and modifications prior to costly field demonstrations and tests.

Propagation in the ionospheric channel is of the multiple-trajectory type and is progressive over time. The result is a degradation of transmissions via this medium, which is emphasized by different noises and jamming signals present in the decametric range. Time shifting of these trajectories reduces the speed of usable modulation. In order to reach rates of 2400 bits per second while preserving a reliable modulation speed, one distributes the information over a great number of subchannels. This technique of orthogonal frequency multiplexing justifies overlapping of the spectrums of a large number of subchannels. By thereby combining error correction convolution coding and coherent demodulation based on the transmission of a posteriori maximum likelihood, we obtained the transmission system described in this article.

THE INFLUENCE OF ANTENNAS AND PROPAGATION ON THE BEHAVIOR OF HF DIGITAL COMMUNICATIONS LINKS INFLUENCE DES ANTENNES ET DE LA PROPAGATION SUR LE COMPORTEMENT D'UN SYSTEME DE TRANSMISSIONS NUMERIQUES EN HF

Bertel, L., Rennes Univ., France; Lebaillif, O., Rennes Univ., France; LeRoux, Y., Centre National d'Etudes des Telecommunications, France; Fleury, R., Centre National d'Etudes des Telecommunications, France; Apr. 1996; 8p; In French; See also 19970000233; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper describes the influence of antennas and propagation on the behavior of H.F. digital communication links. We highlight the role of the antennas with the help of a signal model which takes into account the particularities of propagation in the H.F. range. Results of an experimental link are analyzed and we demonstrate the efficiency of a polarization filtering; this filtering procedure can also be viewed as a vector processing technique allowing a decrease of the BER.

Accurate modeling of radio propagation characteristics in and around built-up urban environments is vital to the successful functioning of surveillance and tracking systems utilizing wireless technology. A vast majority of the software tools currently available to military and civilian users are based on very simple models with fairly limited accuracy and are closed architectures. We discuss the design and development of a software tool that provides: (1) a framework for modelers to incorporate new models and test their hypotheses, and (2) system designers and planners to obtain the propagation characteristics in any environment. The interactive software executes on a workstation, uses topographic maps with building overlays to predict signal coverage and channel characteristics for user-specified antenna locations. Work is in progress to improve the accuracy of the prediction software through better diffraction modeling.

HYBRID DIRECT SEQUENCE-FREQUENCY HOPPING CELLULAR SYSTEM

Kehagias, K., Hellenic Air Force Technology Research Center, Greece; Apr. 1996; 14p; In English; See also 19970000233; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The performance of a hybrid Direct Sequence - Frequency Hopping system for mobile communications is described through computer simulation results. The term hybrid implies the combination

of two separate systems operating together within the same physical channel and not a Direct Sequence (DS) signal whose center frequency hops periodically. The DS part supports the high data rate services and the Frequency Hopping (FH) part the low ones. Initially, a pure DS Code Division Multiple Access (CDMA) system is considered, capable of supporting data communications in a variety of bit rates. The capacity of this system (number of users in the allocated spectrum vs. bit error rate) is calculated. Consequently, low data rate services are removed from the DS system and are transmitted using a FH CDMA technique within the same bandwidth and for the same expected bit error rate performance. Overlapping and non-overlapping hopping patterns are considered. The overall (DS + FH) capacity is calculated and compared with the capacity of the pure DS system. The simulation model for the DS CDMA system is based on the specifications of CODIT (Code Division Testbed), a proposal for next generation's cellular communication system. For the FH CDMA the simulation model is based on a SFH system employing Phase Shift Keying (PSK) modulation.

One of the future applications of smart structures and materials for aircraft of new generation could be the electromagnetic smart skin antennas integrated on the aircraft. Military aircraft contains a proliferation of antennas to support advanced weapon system avionics. A tendency is to reduce the number of antennas sites on an aircraft to a minimum set of multifunction smart skin apertures that will provide equivalent or superior coverage and that will satisfy all the requirements of advanced weapon system avionics. Up to 50 % of the air vehicle could be used for embedment of antennas. Controllable and reconfigurable antennas or conformal antennas are needed for mission flexibility and for reducing component failure or battle damage. Pay-offs are mainly cost saving and weight saving per aircraft with additional properties such as improved low observable performances, supportability and drag reduction, etc... In the first part of the presentation, we will review the present international activity in this area. We will develop some arguments to answering the question: why to do it? In the second part, we will introduce the concept of multifunctional smart skin antenna passing through the elementary radiating element, the adaptive antenna, and the antenna array. The electronic scanning and steering antenna array as well as the conformal antenna array is approached. We end the presentation by a concept of electromagnetic smart skin antenna array that can be developed in the future and integrated to military or civilian aircrafts. During this presentation, a lot of examples will be given for each case. We will address the critical enabling technologies required to implement an electromagnetic smart antenna. We will show the main advantages of such new technologies and concept for military aircraft of new generation (benefit and pay-offs).

MM-WAVE AIRBORNE CLOUD RADARS

Galloway, John, Massachusetts Univ., USA; Pazmany, Andy, Massachusetts Univ., USA; McIntosh, Robert, Massachusetts Univ., USA; Kelly, Robert, Wyoming Univ., USA; Valli, Gabor, Wyoming Univ., USA; Remote Sensing: A Valuable Source of Information; Oct. 1996; 10p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The demand for fine scale radar measurements of clouds from an airborne platform motivated the development of a 95 GHz imaging polarimeter used on a King Air research aircraft. The basic system components and operation of the polarimeter are discussed and the data processing techniques used to obtain conventional measurements of clouds obtained from a melting layer, mixed phase cloud, and

marine stratus cloud during three different field experiments are provided with a description of flight and weather conditions prevailing during each observation.

DIRECT MEASUREMENT OF MICROWAVE PROPAGATION EFFECTS

Stapleton, J., Naval Surface Warfare Center, USA; Kang, S., Naval Surface Warfare Center, USA; Remote Sensing: A Valuable Source of Information; Oct. 1996; 10p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The detection and tracking of low flying cruise missiles by shipboard radars is dominated by environmental effects. Significant temporal and spatial fluctuations in microwave propagation loss have been observed in this low altitude region. In order to better understand these fluctuations and to support the design and test of future naval radars, two microwave propagation measurement systems were developed which allowed the direct measurement of microwave propagation loss. Both systems concentrated on the low altitude region and made measurements at one frequency versus range and across a wide bandwidth for a fixed range. The test data presented in this paper gives a few examples which illustrate the variety of conditions sensed with these systems.

USING REMOTE REFRACTIVITY TO PREDICT TROPOSPHERIC REFRACTIVITY FROM MEASUREMENTS OF MICROWAVE PROPAGATION

Boyer, Donald, Naval Surface Warfare Center, USA; Gentry, Greg, Naval Surface Warfare Center, USA; Stapleton, Janet, Naval Surface Warfare Center, USA; Burk, Stephen, Naval Research Lab., USA; Cook, John, Naval Research Lab., USA; Remote Sensing: A Valuable Source of Information; Oct. 1996; 14p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The direct measurements of vertical profiles of humidity and temperature at various ranges, from which range dependent refractivity structures are derived, are very difficult to obtain onboard a ship, and these profiles are needed in order to predict the performance of a radar system in a coastal marine environment. Recently remote sensing techniques have been proposed which attempt to deduce the refractivity structure over a path by measuring relative signal levels from known emitters. Since in a naval battle group there are known transmitters at different frequencies, whose signals can be monitored by any friendly ship, these radio propagation techniques offer high potential for implementation as part of a shipboard sensor assessment system. In order to derive refractivity fields in the lower atmosphere above the sea surface from measurements of propagation loss, the refractivity profiles must be represented in terms of a small number of parameters. This paper discusses using analytic representations of mean refractivity profiles in the constant flux surface layer of the marine atmospheric boundary layer. The numerical inversion techniques used for obtaining refractivity fields from measurements of propagation loss are also included.

TARGET DETECTION VIA MEASUREMENTS TAKEN BY A TRANSMITTER-INDEPENDENT RECEIVER NETWORK

Farsaris, Nikos J., Crete Univ., Greece; Stavroulakis, Peter P., Crete Univ., Greece; Remote Sensing: A Valuable Source of Information; Oct. 1996; 14p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

In this paper, the technique of target detection via measurements of target range and Doppler shift taken by a set of cooperating radars in an area is extended for potential use on a transmitter independent receiver network (TIRN). This technique is explored for obtaining a detection system that comprises parameters that are substantial for military use: silent operation (undetectability) of an independent bistatic radar receiver, the accuracy of a monostatic radar, and the invulnerability of a distributed computer network.

ASSESSMENT OF NAM, THE NAVY AEROSOL MODEL, FOR VISIBILITY DETERMINATIONS IN INLAND SEAS SUCH AS THE PERSIAN GULF

Gathman, Stuart G., Naval Command, Control and Ocean Surveillance Center, USA; Remote Sensing: A Valuable Source of Information; Oct. 1996; 6p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The effects of aerosol on the transmission of electro-optical energy in the marine atmosphere are very important. The propagation losses caused by aerosols at shipboard level over the open ocean regions of the world are adequately described by the Navy Aerosol Model (NAM). However, inland seas are very different in their geographical situations and the blind application of open ocean developed models to these regions is not necessarily applicable. The US Navy Sharn 110 exercise, which took place in the Arabian Gulf and the Gulf of Oman in February 1995, offered an excellent opportunity to investigate aerosol characteristics in these inland sea regions and compare the results to the open ocean situations as represented by NAM.

SENSING ZERO-RANGE SURFACE SHIP INFRARED SIGNATURES

McGrath, Charles P., Naval Command, Control and Ocean Surveillance Center, USA; Zeisse, Carl R., Naval Command, Control and Ocean Surveillance Center, USA; Remote Sensing: A Valuable Source of Information; Oct. 1996; 8p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Many imaging and non-imaging ship signature prediction codes exist, but few have been validated. In order to properly evaluate target signature and background prediction codes, an accurate database of radiometric images is required. This paper describes a method for acquiring radiometric images of marine targets and correcting the temperatures for atmospheric influences. Low cost remote sensing of infrared signatures is possible using a calibrated laboratory instrument like the AGEMA 900. by using a trusted atmospheric code, such as LOWTRAN or MODTRAN, corrections can be made, and by making remote measurements at two or more distances, the corrections can be fine-tuned to further improve accuracy.

RADIANCE OF THE WIND-RUFFLED SEA

Zeisse, C. R., Naval Command, Control and Ocean Surveillance Center, USA; McGrath, C. P., Naval Command, Control and Ocean Surveillance Center, USA; Littin, K. M., Naval Command, Control and Ocean Surveillance Center, USA; Hughes, H. G., Science and Technology Corp., USA; Remote Sensing: A Valuable Source of Information; Oct. 1996; 12p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A03, Hardcopy; A04, Microfiche

The important contributions to sea radiance are: (1) path emission, (2) sky reflection, (3) sun reflection, and (4) thermal black body emission. The spectral nature of each contribution can be understood

from the infrared properties of the atmosphere and the ocean, and regularities among them can often be explained by Kirchhoff's law. SeaRad, a computer model of sea radiance made by modifying MODTRAN2, takes source and path terms from that code, performs a statistical average over capillary wave slopes, and arrives at a prediction which agrees to within about 1 C with sea radiance measurements in the infrared.

AUTOMATIC CHANGE DETECTION IN SPACEBORNE SAR IMAGERY

Corr, D. G., Defence Research Agency, UK; Whitehouse, S. W., Data Sciences (UK) Ltd., UK; Remote Sensing: A Valuable Source of Information; Oct. 1996; 8p; In English; See also 19970006887; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper describes new techniques for the automatic detection of change within synthetic aperture radar (SAR) images produced from satellite data. The interpretation of this type of imagery is difficult due to the combined effect of speckle, low resolution, and the complexity of the radar signatures. The change detection techniques that have been developed overcome these problems by automatically measuring the degree of change between two images. Changes within a time sequence of images (for example due to demolition or construction; damage, collection or dispersal of mobile assets) can then be determined by logic.

Airborne and spaceborne synthetic aperture radars (SAR) are in use for remote sensing. to hide military targets from being detected by these systems, they might be attacked by electronic countermeasures (ECM). Since SAR systems are characterized by long-time coherent processing of echo signals with integration gains typically in the order of 80 dB, coherent jammers using digital radio frequency memories (DRFM) can generate false targets and camouflage patterns with only moderate jamming powers. The influence of a single coherent deception target, largely exceeding the normal radar echo power received from one single resolution cell, and the generation of a deceptive scene are studied with a simulation model of a generic airborne SAR.

Millimeter wave radiometry has been widely studied for more than twenty years now and can provide specific advantages as compared to infrared/visible imaging and radar detection as well. This paper presents a brief review of millimeter wave radiometry techniques and applications. Recent advances microwave monolithic integrated circuit (MMIC) technology and in focal plane array imagers are particularly highlighted. Research work and CERT-ONERA and DLR-HF which have been active in the field for more than ten years are also described.

The aim of this AGARDograph is to provide a quick overview of practical advances in Multi-Sensor, Multi-Target Tracking (MS/MTT) technology and applications. In order that this AGARDograph could serve as a useful reference for those involved in the design, development, simulation, and applications of the techniques and technology, we have encouraged our authors to take, as much as possible, a tutorial approach. This will provide the general summary of the MS/MTT techniques and technology with emphasis towards practical implementation. Many examples of sensor fusion involve the methodology of merging various track files taken from different sensors. This allows for more consistent, accurate, and reliable tracks than might be possible with any of the individual systems acting alone. Section 1 relates to the important use of sensor fusion prior to establishing a firm track file. By combining raw sensor information, greater discrimination of targets from background may be possible from the augmented body of available information. Tracking and fusion with multiple sensors deals with integration and correlation of data from diverse sources in order to arrive at the best possible situational assessment. In Section 2, we present the tutorial on representative data association and filtering techniques, and also address some of the key initiation issues, approaches and track management methodology that simplify and enhance the practical implementation. Section 3 presents different types of classification algorithms, Bayesian Belief Networks, and Neural Networks covering the complete Automatic Target Recognition process, including fusion, segmentation and classification, that are very promising for real-time, or quasi-real-time systems applications. Section IV covers the handling of Automatic Target Recognition (ATR) test data, deals with an effective tool to support the development of

precision guided munitions, and presents a study of target acquisition and sensor cueing in air-to-air environment. The last Section presents several practical examples of MS/MTT applications.

MULTI-FREQUENCY PHENOMENOLOGY FUSION VIA AN ULTRA-BROADBAND HYBRID SENSOR TECHNOLOGY ENHANCING SURVEILLANCE AND TARGET CLASSIFICATION/ID PERFORMANCE

Ogrodnik, Robert F., Rome Lab., USA; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 3-13; In English; See also 19970012579; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Target phenomenology has observables which occur across the electromagnetic spectrum, and, are linked in their multispectral characteristics through time in the multifrequency observation space, making target phenomenology an ideal candidate for detection domain level signal fusion. That is, given the ability to multispectrally observe target activity, as well as target phenomenon (i.e. missile multispectral launch transits, or, target vehicle body parts which may be dimensionally comparable with the surveillance wave length employed, etc.), an ideal surveillance approach, which supports detection domain fusion, would be to implement a broadband multi-spectrum surveillance sensor technology which could optimize its surveillance sensitivity and operating spectrum simultaneously on differing multispectral phenomena throughout the scenario life profile of the target. This paper addresses such a surveillance technology which exists today at Rome Laboratory. It is based on the integration of passive signal awareness monitoring combining real time signal parameter processing, and, passive coherent radar. This technology readily provides multispectral signal fusion by exploiting in real time background multiple ambient signal sources in order to synthesize a passive radar surveillance capability simultaneously at multiple carrier frequencies (as many diverse spectral sources as there are which constitute the electromagnetic ambient background in the target domain). This allows the target and its associated phenomena to be observed simultaneously in a multispectral fashion, optimizing detection performance whenever an optimal, or near optimal signal source is available for the purposes of enhanced detection and target classification.

INTERACTIVE INTEGRATION OF PASSIVE INFRARED AND RADAR HORIZON SURVEILLANCE SENSORS TO EXTEND ACQUISITION AND FIRM TRACK RANGES

Homan, S. R., Naval Surface Warfare Center, USA; Stapleton, R. A., Naval Surface Warfare Center, USA; Hepfer, K. C., Naval Surface Warfare Center, USA; Headly, R. M., Naval Surface Warfare Center, USA; Stapleton, J. K., Naval Surface Warfare Center, USA; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 14-31; In English; See also 19970012579; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The interactive integration of sensors has shown great promise as a means of significantly improving the range at which ships can detect and acquire high-speed, low altitude Anti-Ship Cruise Missiles (ASCM). Modest sensors, designed for the purpose, have been developed and successfully tested in a field environment. Near-horizon clutter was measured, producing some surprises. A real time integration system has been built and successfully field tested with sensors which had most of the desired characteristics against representative targets. In addition, an unprecedented capability has been developed to measure low altitude propagation to high fidelity as a function of frequency, time, target altitude, radar antenna height and target range, and to measure dynamic infrared refraction effects. This provided a dramatic means to better understand the performance of multi-sensor systems when operated in the field under conditions that produced

anomalous propagation. Improvements in firm track ranges were commensurate with our predictions. A FY95 real time demonstration is planned using a radar with an agile beam antenna.

THE FUSION OF AN IR SEARCH AND TRACK WITH EXISTING SENSORS TO PROVIDE A TRACKING SYSTEM FOR LOW OBSERVABILITY TARGETS

Coates, P. V., Pilkington Thorn Optronics, UK; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 32-47; In English; See also 19970012579; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This chapter covers the topic of the application of multi-sensor fusion, in a modern fighter aircraft, with the objective to improve the performance of pointing and tracking systems. It deals specifically with various techniques, including the use of other sensor data to improve the performance of a passive IR Search and Track (IRST) system to provide an enhanced tracking solution for targets at all ranges, from low observability long range stealth targets to short range pop-up targets. The timing is particularly appropriate in that Pilkington Thorn Optronics is the Technical lead partner in the European International Consortium responsible for the development of the IRST/FLIR system for Eurofighter 2000 (European Fighter Aircraft). It is one of the first airborne passive Electro Optic (EO) detection systems, in Development, capable of simultaneously detecting and accurately tracking multiple targets. It will also have a passive ranging capability. It will be the first time that such a high performance passive target acquisition and tracking system will be available in a modern fighter aircraft. The availability of such systems presents a unique opportunity to combine this information with other onboard sensing systems to obtain a performance 'force multiplier'.

W., Nichols Research Corp., USA; Amphay, Sengvieng, Wright Lab., USA; Sundstrom, Bryce, Wright Lab., USA; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 48-63; In English; See also 19970012579; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The precision guidance of autonomous weapons to fixed High Value Targets (HVT's) and Critical Mobile Targets (CMT's) in high clutter backgrounds under adverse weather conditions represents one of the largest challenges facing the tactical Air Force weapons development community today. Such weapon systems will deny the enemy the cover of weather, just as infrared systems have eliminated the cover of night. One technology that is being explored as a means of addressing this Mission is Millimeter Wave (MMW)/Infrared (IR) sensor fusion. The Armament Directorate of the U.S. Air Force Wright Laboratory has been sponsoring research in the area of MMW/IR sensor fusion for tactical weapon systems since the mid 1980's, much of which was accomplished under joint sponsorship with the U.S. Army Missile Command (MICOM). The purpose of this paper is to address the state of development of tactical Air Force MMW/IR sensor systems, and to demonstrate the results of current risk abatement efforts.

Multiple Target Tracking (MTT) in cluttered environments has been addressed in numerous military aerospace defence and civilian air traffic control studies. Most MTT methods employ models based on simplified assumptions. In this paper, a practical overview of three algorithms for MTT is presented: these are the Nearest-Neighbor (NN), Multiple Hypothesis Tracking (MHT), and Joint Probabilistic Data Association (JPDA) methods. The advantages and limitations of each technique are summarized and suggestions presented for implementation considerations. It should be noted that an efficient Modified MHT applied to Air Defence Tracking is also presented in this AGAR-DOGRAPH.

This chapter presents an algorithm to initiate tracks of a ballistic missile in the initial exoatmospheric phase, using line of sight measurements from one or more moving platforms (typically satellites). The major feature of this problem is the poor target motion observability which results in a very ill-conditioned estimation problem. The Gauss-Newton iterative least squares minimization algorithm for estimating the state of a nonlinear deterministic system with nonlinear noisy measurements has been previously applied to the problem of angles-only orbit determination using more than three observations. A major shortcoming of this approach is that, convergence of the algorithm depends strongly on the initial guess. By using the more sophisticated Levenberg-Marquardt method in place of the simpler Gauss-Newton algorithm and by developing robust new methods for obtaining the initial guess in both single and multiple satellite scenarios, the above mentioned difficulties have been overcome. In addition, an expression for the Cramer-Rao lower bound on the error covariance matrix of the estimate is derived. We also incorporate additional partial information as an extra pseudo-measurement and determine a modified maximum likelihood estimate of the target state and the associated bound on the covariance matrix. In most practical situations, probabilistic models of the target altitude and/or speed at the initial point constitute the most useful additional information. Monte Carlo simulation studies on some typical scenarios were performed, and the results indicate that the estimation errors are commensurate with the theoretical lower bounds, thus illustrating that the proposed estimators are efficient.

This chapter discusses a multi-radar air defense system implementation that utilizes central-level observation (plot) processing and Multiple Hypothesis Tracking (MHT) data association. The chapter begins with an overview of the air defense system application and a discussion of the reasons MHT data association has been chosen. Next, the transformation of plot data from multiple distributed radars to a common stereographic coordinate system is described and the approach to registration is outlined. The mathematical basis and the implementation logic for the track-oriented MHT algorithm are

described. This includes a discussion of the clustering, pruning and merging methods that have been developed to make implementation feasible. The manner in which the output of the MHT tracker is presented to the user is also described. A number of features make the multi-radar air defense application more complex than single sensor systems. These include the variety and asynchronous nature of the input data, the potential for variable and heavy clutter densities and stringent false track confirmation requirements. This chapter will present the specific methods that have been developed to adapt the general MHT algorithms to these requirements. It will show how false track requirements can be related to the MHT track confirmation threshold through the use of the Sequential Probability Ratio Test (SPRT). Finally, analytic and simulation methods that have been developed and applied to predict performance of an air defense tracking system are discussed and representative results are presented.

MULTISENSOR TRACKING AND FUSION WITH MTI RADARS

Chang, Kuo-Chu, George Mason Univ., USA; Bar-Shalom, Yaakov, Connecticut Univ., USA; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 121-129; In English; See also 19970012579 Contract(s)/Grant(s): N00014-91-J-1950; F49620-95-1-0229; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Multisensor tracking and data fusion deals with combining data from various sources to arrive at an accurate assessment of the situation. Technical difficulties in performing multisensor tracking and fusion include not only ambiguous data, but also disparate data sources. The tracking and fusion problem is further complicated by the facts that targets may not be detected by some sensors, dense false alarms and clutter detections may be present, and the target model may not be known exactly. In this chapter, a multitarget tracking problem which involves data obtained from multiple MTI radars is considered. A tracking and fusion algorithm which takes into account the uncertainties in both data origin and target dynamics under a dense clutter environment is presented.

The central elements of this paper are the development of a statistical approach to the problem of track fusion, specifically, track correlation, and system track maintenance in distributed command and control systems. This paper presents: (1) the functional requirements for track management in conventional air defense systems and extended air defense systems (which include low-observable aircraft, cruise missile, and tactical ballistic missile defense); (2) the theoretical foundations for the sequential, multiple hypothesis decision processes used in the FAAD C(sup 2)I, IADS and NATO AEW Integration Programs; (3) track maintenance in distributed systems, and (4) a discussion of the practical aspects of the application of the theory to systems constrained by current data link message standards. The essential theory for sequential correlation decisions is based on the sequential probability ratio test for multiple alternative hypotheses. The decision statistics and criteria are derived together with the theoretical performance trade-offs among type 1 and type 2 errors and decision times.

CLASSIFICATION THROUGH COMBINING UNCERTAIN MULTIPLE-SENSOR DATA CLASSIFICATION PAR FUSION DE DONNES INCERTAINES MULTI-SENSEURS

Appriou, Alain, Office National d'Etudes et de Recherches Aeronautiques, France; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 149-160; In French; See also 19970012579; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This paper discusses a multiple-sensor analysis which is used to recognize one situation among a certain number of a priori identified hypotheses, for the identification of a target, for example, that must be capable of extracting the best part of all previously available learning. The traditional method of processing, especially probabilistic, still remain limited by the failure of representation of this learning sessions when the conditions of observation develop in a way that is not carefully controlled. In that case one must resort to uncertainty techniques, and in particular to the Theory of Evidence which will obtain the most open framework in this context. Its implementation, however, will lead to the delicate problem of interpretation of available information, considering the concepts that is allows one to deal with. Therefore it is an axiomatic search for the most pertinent solutions that we are suggesting here for two types of complementary problems, which are united by a generic processing concept for managing feasibility of the data that are supplied. The benefit of this approach is evaluated based on several simple simulations.

THE USE OF BAYESIAN BELIEF NETWORKS TO FUSE CONTINUOUS AND DISCRETE INFORMATION FOR TARGET RECOGNITION, TRACKING, AND SITUATION ASSESSMENT

Stewart, Leland, Lockheed Martin Palo Alto Research Lab., USA; McCarty, Perry, Jr., Lockheed Martin Palo Alto Research Lab., USA; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 161-166; In English; Signal Processing, Sensor Fusion and Target Recognition, 21 Apr. 1992; Sponsored by International Society for Optical Engineering, USA; See also 19970012579; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper describes the use of Bayesian Belief Networks for the fusion of continuous and discrete information. Bayesian belief networks provide a convenient and straightforward way of modeling the relationships between uncertain quantities. They also provide efficient computational algorithms. Most current applications of belief networks are restricted to either discrete or continuous quantities. We present a methodology that allows both discrete and continuous variables in the same network. This extension makes possible the fusion of information from, or inferences about, such diverse quantities as sensor output, target location, target type or ID, intent, operator judgment, behavior profile, etc.

Target acquisition in a high clutter environment in all-weather at any time of day represents a much needed capability for the air-to-surface strike mission. A considerable amount of the research at the Armament Directorate at Wright Laboratory, Advanced Guidance Division WL/MNG, has been devoted to exploring various seeker technologies, including multi-spectral sensor fusion, that may yield a cost efficient system with these capabilities. Critical elements of any such seekers are the autonomous target acquisition and tracking algorithms. These algorithms will allow the weapon system to operate inde-

pendently and accurately in realistic battlefield scenarios. In order to assess the performance of the multi-spectral sensor fusion algorithms being produced as part of the seeker technology development programs, the Munition Processing Technology Branch of WL/MN is developing an algorithm testbed. This testbed consists of the Irma signature prediction model, data analysis workstations, such as the TABILS Analysis and Management System (TAMS), and the Modular Algorithm Concept Evaluation Tool (MACET) algorithm workstation. All three of these components are being enhanced to accommodate multispectral sensor fusion systems. MACET is being developed to provide a graphical interface driven simulation by which to quickly configure algorithm components and conduct performance evaluations. MACET is being developed incrementally with each release providing an additional channel of operation. To date MACET 1.0, a passive IR algorithm environment, has been delivered. The second release, MACET 1.1 will be presented in this paper using the MMW/IR data from the Advanced Autonomous Dual Mode Seeker (AADMS) captive flight demonstration. Once completed, the delivered software from past algorithm development effort will be converted to the MACET library format, thereby providing an on-line database of the algorithm research conducted to date.

STUDIES AND SIMULATIONS ON SENSOR FUSION AND CUEING FOR FIGHTER APPLICATION

Avale, Massimo, Alenia Aeronautica, Italy; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 224-232; In English; See also 19970012579; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

A method to implement Sensor Fusion and Sensor Cueing on an advanced fighter aircraft is described in this paper. Starting from a short introduction concerning the general aspects and theory of Sensor Fusion, the paper presents some choices adopted during the development of the Sensor Fusion process at ALENIA AERONAUTICA System Technology dept. Sensor Cueing will be also introduced and some particular cases of interest for a fighter aircraft will be discussed. The performances of the adopted solutions are then discussed on the basis of some experimental results obtained using a simulation tool. An evaluation of the overall Sensor Fusion process performance and some considerations about possible alternatives will conclude the work.

In this paper, an efficient Multiple Hypothesis Tracking (MHT) algorithm has been developed and implemented. This algorithm is a modified version of MHT combined with an N-scan back pruning approach. The principal objective of this modification is to effectively reduce the large number of hypotheses in the original MHT thereby yielding a fast tracking algorithm which requires moderate computing resources. The modified MHT algorithm has been extensively tested against numerous sets of real radar measurements. These real radar data contain complex tracking scenarios such as trajectories of several fighter aircraft going through high-g maneuvers, crossing tracks and close formation in a cluttered environment. This paper will demonstrate the performance of the modified MHT algorithm against a set of real radar data. Descriptions of the radar data and the extent of the clutter are provided. The effectiveness of the modified MHT algorithm in handling maneuvering targets will also be discussed.

LOW COST MULTI-SENSOR SUITES FOR SURVEILLANCE AND WEAPON GUIDANCE

Suresh, B. R., Alliant Techsystems, Inc., USA; Multi-Sensor Multi-Target Data Fusion, Tracking and Identification Techniques for Guidance and Control Applications; Oct. 1996, 251-267; In English; See also 19970012579; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

With the changing geo-political landscape, there is an ever increasing need for low-cost sensors for application to surveillance systems and weapon guidance. Typically, these applications require Mission Millimeter Wave (MMW) radars, IR imaging sensors, ladars and acoustic sensors as well as signal processing algorithms and high throughput miniature processors. The emphasis should be on developing low-cost individual sensors. The system applications then typically involve a suite of low-cost multiple sensors. The fusion of information from these sensors provides superior performance and an overall cost-effective product.

The modern air superiority aircraft is faced with ever increasing threats and more capable targets. To be effective against them, it needs to know what and where they are as early as possible during any encounter. It must do this during day and night, in all weathers, in hostile counter measure environments and in the presence of clutter. The aircraft will receive large amounts of information from multiple sensors and data communications systems. If the information is to be used effectively to the benefit of the mission, it must be aligned, correlated, consolidated and presented to the crew in a meaningful form. A model is offered of tactical situation awareness processing as it might be embedded in a future avionics system. It shows Sensor Data Fusion in relation to sensors and communications, to situation and threat assessment and to sensor and mission management. It shows the flow of data around the sub-system as it creates and maintains the tactical situation database and ranks the information therein in order of importance to the mission. The requirements placed on sensor data fusion by air superiority operations are discussed. These are dominated by particular features of the tactical aircraft platform and its mission. A computer test harness, developed by BAe Defence, Military Aircraft Division, is described, along with built in tools which calculate test statistics. The harness was developed as part of a programme of studies carried out by the Mission Systems group of the Product R&D team within the Systems Engineering Department at BAe's Warton unit in Lancashire, U.K. Examples of the results which were obtained when an air to sensor data fusion model was evaluated are reproduced.

As a result of various system studies and work on experimental and operational Data-Links for UAV and missile applications, MATRA CAP SYSTEMS of France and Daimler-Benz Aerospace AG 'SENSOR SYSTEMS GROUP' of Germany are cooperating for the development of a high performance Data-Link for a franco-german UAV system. The organization formed for the development of this Data-link comprises a joint system engineering team for refinement of

the overall data link design, definition of interface and specification of requirement to ground data terminal and air data terminal. Separate project teams in the two companies. One company responsible for ground station development, one company for development of airborne station. Maximum commonality by using identical sub-components in both stations as far as possible. Joint program direction comprising the program managers of both companies. Based on the system work, which was done in the two companies in order to win that development contract and the knowledge of previous data links which are in development or production for missile systems, the subject of data links for UAV applications is presented here.

COMMUNICATION BLACKOUT DURING EARTH-ATMOSPHERE ENTRY OF CAPSULES

Boukhobza, M., Aerospatiale, France; May 1995; 8p; In English; See also 19970026365; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Communication blackout that occurs when space capsules enter the earth atmosphere is discussed. This paper has three sections. The first section describes: the communication blackout phenomenology, computer programs used at Aerospatiale Espace & Defence to predict the plasma characteristics, and the radioelectric attenuations effects in communication blackout. The second section deals with altitude ranges and encountered problems during the atmosphere entry of capsules. Examples of communication blackout observed during entry of APOLLO and SOYOUZ vehicles are summarized in the last section.

The overall aim of much of the Acoustic & Noise research is to minimize the risk of hearing damage whilst maximizing the operational communications capability, with communications meaning all necessary signals to the pilots' ear. Calculations show that by using next generation active noise reduction technology in the flying helmet, producing higher levels of active reduction or combinations of active & passive attenuation, it is possible to reduce the noise levels at the pilots ear to around 75 dB, such that the hearing damage risk is essentially reduced to zero. The reduction of noise levels at the ear is also fully compatible with improving speech & non-speech communications. At the talker & signal input end - at the microphone - signal processing approaches are needed to provide adequate signal to noise

ratios for transmission, not only for the reception by humans, but also for the recognition by machines, whether they are part of a human centered system (e.a. Vocoder) or a machine centered system (e.g. Voice Recognition Systems). At the listening end, research into means of noise reduction, either active or passive - or, more likely, and tested Auditory Icons, will require the use of higher quality transducers in the helmet earshell, as will the use of good performance ANR, and this will support the move towards higher speech intelligibility. Overall, the progress of technology and computing, that is now available in the acoustics arena, will provide a strong capability to allow the enhancement of operational crew performance by the use of the auditory mode as a synergistic supplement to the more heavily utilized visual senses.

DESIGN CONSIDERATIONS FOR 3-D AUDITORY DISPLAYS IN COCKPITS

Gilkey, Robert H., Wright State Univ., USA; Simpson, Brian D., Wright State Univ., USA; Isabelle, Scott K., Armstrong Lab., USA; Anderson, Timothy A., Armstrong Lab., USA; Good, Michael D., Honeywell Technology Center, USA; Jun. 1997; 10p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Potential cockpit applications of 3-dimensional auditory displays have generated considerable interest. These applications include: increasing speech intelligibility by spatially separating communication channels, providing a navigation beacon, directing pilots' attention to targets and threats, enhancing situational awareness by cuing a wingman's location or indicating an imminent collision, or even providing an auditory attitude indicator. However, cockpit noise and the complexity of the signals to be localized can adversely affect sound localization performance and may limit the effectiveness of these displays. We review the results of our experiments on sound localization in noise and the localization of speech signals with the head stationary, which indicate that although the ability to distinguish left from right can be quite accurate in adverse situations, often the accuracy of elevation judgments decreases and the number of front/back confusions increases with relatively small deviations from ideal conditions. The implications of these performance limitations for the design of auditory displays and potential strategies for enhancing performance will be discussed.

In the experimentation described here, two types of information that can make it possible to locate a threat were studied in an aeronautical context. Visual information, consisting of an arrow pointing toward the threat, involving a relatively high-level cognitive mechanism, was presented on an HMD (fully feathering propeller). A more perceptual location aid, based on 3D sound, was used alternately or simultaneously. The study was conducted in the context of cooperation between Sextant Avionique, Armstrong Laboratory, and IMASSA/CERMA. The purpose was to evaluate the effectiveness of these two modes of information in a flight simulator and to test the hypothesis of a synergy between them. The results presented here relate more particularly to the phase of orientation toward the threat. The analysis of data received during the experiment shows that the visual and sound information is equivalent and that there is an additive synergy.

This synergy is revealed by a significant improvement of the performances of the test subjects when the two modes are presented in an additive and simultaneous fashion.

EVALUATION OF A THREE-DIMENSIONAL AUDITORY DISPLAY IN SIMULATED FLIGHT

Bronkhorst, A. W., Institute for Human Factors TNO, Netherlands; Veltman, J. A., Institute for Human Factors TNO, Netherlands; Jun. 1997; 6p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Modern signal processing techniques allow headphone sounds to be processed in such a way that they seem to originate from virtual sound sources located in the three-dimensional space around the listener. By using head tracking devices, it is even possible to create a stable virtual acoustic environment that takes (head) movements of the listener into account. One interesting application of 3D sound is that it can be used to support situational awareness by generating virtual sound sources that indicate positions of relevant objects (e.g. targets or threats). This application was investigated in two flight simulation experiments in which the 3D auditory display, used as a radar display, was compared with 2D and 3D visual radar displays. A target localization task was employed, in which the subject, who flew a fighter aircraft, had to locate and follow another, suddenly appearing aircraft as quickly as possible. Dependent variables were the search time and a subjective workload score, obtained after each trial. In the second experiment, also the deviation from the optimal track toward the target and the performance on a secondary task were scored. Results show that search times and workload are similar for 3D auditory and 2D visual displays. Search times for the 3D visual display were smaller. Simultaneous presentation of auditory and visual displays gave clearly improved performance in case of the 2D visual display, but only minimal improvement with the 3D visual display. The results demonstrate the effectiveness of a 3D auditory display used as a radar display, but indicate that further development is required to reach the performance level of advanced 3D visual displays.

FLIGHT DEMONSTRATION OF AN INTEGRATED 3-D AUDITORY DISPLAY FOR COMMUNICATIONS, THREAT WARNING, AND TARGETING

McKinley, Richard L., Armstrong Lab., USA; D'Angelo, William R., Armstrong Lab., USA; Ericson, Mark A., Armstrong Lab., USA; Jun. 1997; 14p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

Recent laboratory experiments have demonstrated significant increases in visual target acquisition performance when the subjects have been aided by 3-D audio cueing. The USAF Armstrong Laboratory's 3-D audio display system was integrated with a helmet mounted display system on a Navy/Marine TAV-8B Harrier for a joint Air Force/Navy flight demonstration. The 3-D audio system has the capability of synthesizing signals that when presented over headphones give the user the illusion that the sound is emanating from some external location. These synthesized signals can be configured to emanate from selected known sources to indicate their location on the ground and in the air. Military aircraft applications of 3-D audio include threat location warning, wingman location indication, spatially separated multi-channel communications, and audio target location indications. For this flight demonstration, the Armstrong Laboratory 3-D audio system implemented spatially separated communications, threat location cueing, and target location aiding. Laboratory experiments of combined audio-visual search performance resulted in target acquisition time reductions of approximately 50 percent and workload reductions of approximately 20 percent. In March 1996, the data collection portion of the flight demonstration was initiated. The integration of the

3-D audio system into the TAV-8B, the laboratory experimental results, and the preliminary results of the flight demonstration are presented in addition to recommendations for future research and flight tests.

COORDINATED SPEECH TECHNOLOGY RESEARCH OF NINE NATO COUNTRIES IN RESEARCH STUDY GROUP RSG.10

Steeneken, H. J. M., Institute for Human Factors TNO, Netherlands; Gagnon, L., Department of National Defence, Canada; Jun. 1997; 6p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The relevance of the application of speech and language technology in the military is considered. The Research Study Group initiates and coordinates research on these applications, focused on the specific adverse military conditions. Specifically multi-lingual applications with non-native speakers, adverse environmental conditions (high noise, g-forces, vibration), and stress conditions (workload, battlefield) do reduce the performance of advanced applications. For example secure voice at low bit-rates, speech recognition in command and control, speaker/language recognition for intelligence and translation in joint force conditions are major applications to be studied. Nine NATO countries participate in this effort.

SPEECH LANGUAGE HEARING TEST RESULTS OF ACTIVE DUTY PILOTS FAILING THE PURE TONE AUDIOMETRY LIMITS OF ICAO GUIDELINES: METHOD, PROBLEMS AND LIMITS TO VERIFY THE WAIVER STATUS

Hanschke, W., German Air Force, Germany; Jun. 1997; 4p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A01, Hardcopy; A03, Microfiche

Adequate hearing is essential for communication in flight and rapid and accurate assessment of warning tones in the cockpit. Waiver is permitted, when hearing is adequate to permit essential communication in flight. The Freiburger speech language hearing test method gives the opportunity to verify the intelligibility in a standard proven manner with the possibility to add aviation related necessities. A higher safety standard could be refined by replacement of the former subjective aeromedical hearing methods.

IMPROVED SPEECH INTELLIGIBILITY IN AIRCRAFT NOISE DUE TO ALTITUDE

Wagstaff, Anthony S., Royal Norwegian Air Force, Norway; Jun. 1997; 6p; In English; See also 19970026380; Sponsored in part by Norwegian Air Ambulance; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Few studies have addressed effects of altitude and noise combined, although these two effects are inherent parts of all aviation. The few published studies that have addressed altitude effects on hearing function have mainly focused on using gas mixtures, and have demonstrated inconclusive results. The present study was designed to assess the effect of altitude on speech intelligibility in aircraft noise. The primary hypothesis was a predicted detrimental, hypoxic effect on speech intelligibility in noise. Eight male subjects with normal hearing were fitted with an aviation headset specially adapted for use with the audiometer. Pure-tone audiometry, as well as speech audiometry in noise, was performed at 0, 10,000, 13,000, and 16,000 ft. simulated altitudes in a hypobaric chamber. The 4 test altitudes were performed double blind with respect to audiometry operator and test subject. Arterial blood gases were measured using an intra-arterial catheter and

tympanometric measurements verified full middle ear equilibration. Noise levels were monitored and logged throughout all experiments. A substantial increase in speech intelligibility in noise due to altitude was found in this study. The physical effect of barometric pressure on noise causing an increased signal-to-noise ratio was found to greatly outweigh any hypoxic detrimental effect.

VULNERABILITY OF FEMALE SPEECH PRODUCED IN OPERATIONAL NOISES

Nixon, C. W., Armstrong Lab., USA; Morris, L. J., Armstrong Lab., USA; McCavitt, A. R., Armstrong Lab., USA; McDaniel, M. P., Armstrong Lab., USA; Anderson, T. R., Armstrong Lab., USA; McKinley, R. L., Armstrong Lab., USA; Yeager, D. G., Armstrong Lab., USA; Jun. 1997; 12p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

This study quantified the speech intelligibility differences in high level noise due to gender. Female speech was always less intelligible than male speech and the differences grew with increased levels of the noise. Intelligibility of both male and female speech differed with aircraft noise spectrum. These gender differences caused no impact at the lower levels of noise, however they do constitute a problem at the highest levels. The application of active noise reduction technology and replacement of the M-87 with the M-169 noise canceling microphone should neutralize most of these impacts. The perception of LPC-10 and CVSD vocoded female speech was essentially the same as male speech. There were no significant differences between the recognition accuracy of male and female speech for either the ITT or IBM automatic speech recognition system.

A Voice Communication Effectiveness Test (VCET) was developed for relating voice communications performance to the effective completion of tasks with varying complexity, criticality, and time constraints. VCET is based on information theory and was initially developed for military applications. This metric accounts for the information required for task completion, the time available for the task, and the criticality or cost of an error relating to the quality of the communication channel. It can quantify the effects of competing workload on voice communications and it encompasses a wide range of voice communications systems and equipment, noise environments, and military missions. The rationale, development, and performance of these powerful analytical tools with applications in both the military and civilian communities were described. VCET shows great promise as the first true voice communication effectiveness test measuring not only intelligibility, but also information transfer with or without time dependency.

VOCAL AGITATION AS A PREDICTOR OF EMOTION AND STRESS

Allerhand, M. H., MRC Applied Psychology Unit, UK; Patterson, R. D., MRC Applied Psychology Unit, UK; Jun. 1997; 10p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

This paper reports an application of a computational auditory model to measure vocal agitation in speech automatically, and to relate it to the perceived stress in recordings of pilots operating under

adverse conditions. Results of a short-time correlational experiment show significant correlation ($r = 0.765$; p is less than .001) between measured and perceived vocal agitation. It is also shown that time-integrated vocal agitation corresponds well with perceived stress over a period of the order of 18s.

EFFECTS OF HELICOPTER CABIN NOISE UPON HF VOCODER SECURE SPEECH SYSTEMS

Rogers, I. E. C., Defence Research Agency, UK; Rood, G. M., Defence Research Agency, UK; Jun. 1997; 10p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

An increasing number of military aircraft are being provided with secure (encrypted) systems for air-to-air, air-to-ground and ground-to-air communications. Most secure HF radio channels use a Linear Predictive Coder (LPC-10 Vocoder) to parameterize the talker's speech, and this digital data is then encrypted before being transmitted over the HF radio link. At the receiver, the data is decrypted and fed into a second vocoder, where the speech parameters transmitted are used to produce a representation of the original speech signal. The vocoders transmit the digitized data at 2.4kbits/sec according to the NATO STANAG 4198 interoperability standard. Studies at DRA Farnborough have identified that the presence of helicopter noise at the microphone input to the transmitting vocoder reduces the intelligibility of the vocoded speech transmitted, and that the reduction is dependent on the relative levels of the speech and noise at the microphone (i.e. the speech to noise ratio, SNR). These assessments have been conducted using Diagnostic Rhyme Test (DRT) techniques. DRA have investigated techniques to enhance the performance of vocoders using digital processing techniques. DRT and user acceptability assessment trials have been conducted to assess the effects of these techniques on LPC-10 vocoder performance and the results of this work will be presented.

VOICE RECOGNITION IN ADVERSE AIRCRAFT COCKPIT ENVIRONMENTS

South, A. J., Defence Research Agency, UK; Jun. 1997; 10p; In English; See also 19970026380; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

A speech recognition system has been flown in a two seat Tornado strike aircraft and assessments made of the recognition accuracy under normal, terrain following and 4G turning flight. Word accuracies averaged some 96% under normal flight, and 95% under terrain following. During 4G turns the recognition levels dropped to around 80%. Subsequent speech recordings made on the centrifuge at the RAF School of Aviation Medicine consisted of lists of digit strings and typical Direct Voice Input command phrases. Recordings were made at up to 8G, using four different levels of anti-G protection. The subjects were five male RAF personnel, and one female. The digit string lists were used to test a speaker-dependent whole word speech recognizer at up to 6G. The results will be presented for protection using standard and full coverage anti-G garments, and with the use of positive pressure breathing. Possible solutions to the lower accuracy rates at higher G levels and with pressure breathing are discussed.

This paper discusses the performance optimization of an ITT VRS-1290 continuous speech, speaker dependent speech recognition system that was flight tested in a NASA Lewis Research Center OV-10A aircraft. A 53-word vocabulary was tested with twelve pilots using an M-162 microphone headset on the ground and under 1g and 3g flight conditions. Digital Audio Tape (DAT) recordings were made of both the subjects' input and ambient background noise. Noise levels in the rear cockpit were in excess of 115 dB, with signal-to-noise ratios measured as low as 12 dB. During the early stages of the flight test, performance of the ITT system was poor, with some subjects achieving below 60% recognition accuracy. The DAT recordings became a critical element in the troubleshooting and optimization of the ITT system. A combination of input gain, noise calibration, and ITT recognizer engineering parameters were adjusted based on DAT testing to achieve an average word accuracy of 97.7% in the 1g condition and 97.1% in 3g across all subjects.

HIDDEN USABILITY ISSUES IN SPEECH INTERFACES

Cook, Malcolm J., Abertay Univ., UK; Cranmer, Charles, Abertay Univ., UK; Milton, Carol-Ann, Abertay Univ., UK; Finan, Robert, Abertay Univ., UK; Sapeluk, Andy, Abertay Univ., UK; Jun. 1997; 30p; In English; See also 19970026380; Sponsored in part by European Social Fund; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The increasing power and sophistication of speech recognition and speech synthesis has encouraged speculation that human factors problems in implementing speech interfaces will diminish dramatically as technological develops. Advanced speech interfaces have been investigated and are currently being integrated into prototypes for advanced civil and military cockpits. The reason for the introduction of speech-based interfaces is to increase the time available for head-up flight and, thereby, to improve flight performance and safety. The advantage which is claimed for delivering information via speech-based interfaces is a reduction the vast quantities of information normally presented in visual displays in the cockpit and the release of the pilot from head down management of cockpit systems. Directly or indirectly, the benefits of splitting information delivery and data command/entry across modalities are often justified in terms of independent information processing. The independent nature of the processing in turn assumes there will be no interference between tasks or degradation in performance. Pilot research by the authors indicates that there are problems related to memory and workload that are present in current technology and will remain in future solutions with speech-based interfaces. These problems will remain in even though recognition accuracy is increased because they reside in the limits of the human operator to manage multi model environments. In a simulated multi-task environment self-reports and performance a moderate to high levels workload workload with multi-model interfaces have shown that overall performance with speech-based interfaces is degraded. The use of multi-model interfaces resulted in degraded performance on tasks requiring extended processing of information and recall of information from memory.

POSSIBILITIES AND LIMITATIONS OF SPACEBORNE SAR WITH RESPECT TO MILITARY RECONNAISSANCE

Keydel, W., Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Jun. 1997; 10p; In English; See also 19970026418; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

SAR systems for military applications have to be considered with respect to the requirements resulting from specific scenarios which are estimated by the objects to be observed. The most important

requirements for military reconnaissance satellites are the geometrical resolution, the dimension of the covered area as well as timeliness and the coverage repetition. The latter is strictly dependent on the satellites orbit, which leads to power requirements. Synthetic aperture radar systems have potential resolution capabilities nearly comparable with optical systems. The image resolution as well as its contrast is dependent on weather conditions and optical vision. Foliage penetration, principally, is possible and lower frequencies allow to some extent surface penetration also. Main restrictions of SAR are related to data processing, data handling and power requirements. Automatic real time image analysis as well as image interpretation is not yet possible at all. However, special modes like Scan-SAR, Interferometry, Look Steering and Spot Light, as well as multi mode and multi satellite concepts seem to be able to overcome many limitations and to increase the efficiency of SAR systems for military purposes drastically.

RADAR BACKSCATTER STATISTICS FROM THE SEA SURFACE: IMPLICATIONS OF SIR-C/X-SAR OBSERVATIONS FOR MARITIME SURVEILLANCE

Macklin, J. T., GEC-Marconi Research Centre, UK; Stapleton, N. R., GEC-Marconi Research Centre, UK; Robertson, N. A., Defence Research Agency, UK; Ringrose, R., Defence Research Agency, UK; Jun. 1997; 8p; In English; See also 19970026418

Contract(s)/Grant(s): DRA-CSM2/155; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Multi-channel synthetic-aperture radar (SAR) observations from the SIR-C/X-SAR experiment in the N. E. Atlantic (April 1994) are analyzed, to test models of both the mean and the distribution of radar backscatter from the sea surface. The data cover incidence angles from about 20 deg to 40 deg, and wind speeds from about 5 to 10 m/s (exp 1). Empirical and theoretical models of the mean fit the data well at C band, to an accuracy of 1 - 2 dB. Discrepancies at L and X bands point to needs for better empirical models at these frequencies, and for modifications to existing descriptions of short-wave spectra in theoretical models. Single-look SIR-C/X-SAR data (spatial resolution approximately 7 - 10 m) fit well to a K distribution, but multi-look data (spatial resolution approximately 25 m) fit a lognormal distribution. The observed second moments can be explained by the modulations of resolved ocean-surface waves, but only if relatively large hydrodynamical modulations are assumed. Swell-wave modulations are sometimes significantly larger at X band than at C and L bands. The implications of these results for the false-alarm rates in marine-target detection are discussed.

POSSIBLE FEATURES OF NATO COMMUNICATIONS SATELLITE GAP FILLER

Ricci, P., Alenia Spazio S.p.A., Italy; Franzosi, A., Alenia Spazio S.p.A., Italy; Jun. 1997; 10p; In English; See also 19970026418; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

NATO strategy is changed and emphasis is now on Multinational Groups, Mobile and Rapid Reaction Forces which are easily deployable in the crisis area and capable of rapid responses. In the new political scenarios, satellites are the only assets which can provide the timely and reliable communications required to exercise the command and control of deployed forces. It is also clear that space is the fourth component of a military operation and the role of communication satellites is of crucial importance for peace keeping, peace making operations and for the conduct of conflicts in areas where ground communications facilities can not be easily set up or are not any longer available. NATO communications satellites are expected to terminate their operational life around 2002/2003 and a decision is to be made on how to procure the communications capacity required to support NATO operations after that period. Based on the above consideration, we will examine a range of solutions to overcome the possible lack of

NATO MILSATCOM assets in the next few years.. In addition the possible solutions will be based on the criteria of using entire units and packages available off the shelf as many as possible for the construction of the NATO Gap Filler Satellite.

EXPERIMENTAL ANTIJAMMING RESULTS OF AN ON-BOARD SATELLITE TELECOMMUNICATIONS ANTENNA RESULTATS EXPERIMENTAUX D'ANTIBROUILLAGE D'UNE ANTENNE EMBARQUEE DE TELECOMMUNICATION PAR SATELLITE

Tutard, P., Thomson-CSF, France; Poux, J. P., Thomson-CSF, France; Croq, F., Alcatel Espace, France; Jun. 1997; 10p; In French; See also 19970026418; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

The next generation of military telecommunications satellites must make it possible to improve the effort to meet operational requirements by ensuring support primarily of simultaneous theaters of operations and powerful protection against electromagnetic jamming. An anti-jamming antenna demonstrator model, for SHF reception on board a satellite, was developed and built under the sponsorship of the General Delegation of Armament, Alcatel Espace, and THOMSON-CSF. This active multibeam antenna is combined with a self adaptive anti-jamming unit that employs a so-called 'secondary lobe opposition' technique. The analysis and simulation of several solutions led to the choice of an antenna with a reflector equipped with an active lens, combined with secondary lobe opposition treatment. The secondary lobe opposition eliminates jamming on the principal channels by means of the weighted addition - via the analog method - of the latter with the auxiliary channels intended to pick up the jammers. Adequate weighting is calculated numerically.

Future generations of military satellite communications systems will require vast protection against jamming and a greater facility for interconnections between nations of different types. Meeting these needs calls for an anti-jamming computer to handle the transmission function. This computer performs different functions numerically: high-frequency numerical acquisition of sampling of data blocks coming from a transmission channel or channels; and intensive anti-jamming processing, requiring especially the formation of inter-correlation matrixes and the resolution of linear systems.

An Integrated Electro-Optical Sensor Simulation (EOSS) capability has been developed which can analyze the performance of space-based, surveillance systems at both the sensor and constellation levels. For sensors operating in an infrared-blocking band against an earth background, target detection is generally limited by sensor output variations known as clutter, which results from the interaction of the sensor with background scene structure such as clouds. EOSS uses a scene generation model to create the required cloud scenes

and an end-to-end simulation of the imaging chain to evaluate the impact of these backgrounds on sensor performance. Results from these detailed simulations are combined within a constellation-level analysis tool to provide global sensor coverage and target detection statistics as a function of sensor design, background level, target parameters, and constellation size and type. This simulation capability has been used to determine theatre missile detection and report times for a representative spacebased, infrared surveillance architecture. The trade between sensor performance and payload weight has also been explored, with uncertainties in the background clutter modeling playing a key role in driving the sensor designs in the direction of heavier and more expensive payloads.

APPLICATION-SPECIFIC BANDWIDTH COMPRESSION FOR DISSEMINATION OF IMAGE DATA

Danahy, S. B., Aerospace Corp., USA; Hou, H. S., Aerospace Corp., USA; Habibi, A., Aerospace Corp., USA; Bassett, E. M., III, Aerospace Corp., USA; Jun. 1997; 8p; In English; See also 19970026418; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Image data collected in support of NATO forces continues to increase in quantities which exceed the available communications links. To address the mismatch in data volumes and communications lines, bandwidth compression techniques are being developed and implemented. We refer to the systems, both the hardware and software, used for compression and decompression of image data as codecs compressor/decompressor systems. Codecs have traditionally been optimized for a number of different criteria, including: the speed of decompression, ability to recover from transmission errors, preservation of specific image attributes, maintenance of visual quality, and communication factors including target bit rates. This paper will examine a family of codec systems in terms of military support, and an analysis of selected codecs will be performed. The analysis is based on an expanded optimization criterion. The new codecs criterion includes the maintenance of image quality as related to machine processing for image understanding and information extraction. Consideration will also be given to the suitability of space implementation for the compression system.

RADAR SIGNATURE ANALYSIS AND IMAGING OF MILITARY TARGETS L'ANALYSE DE LA SIGNATURE RADAR ET DE LA VIDEOSCOPIE DE CIBLES MILITAIRES

Apr. 1997; 196p; In English; In French, 7-10 Oct. 1996, Ankara, Turkey; See also 19970026664 through 19970026682 Report No.(s): AGARD-CP-583; ISBN 92-836-0039-8; Copyright Waived; Avail: CASI; A09, Hardcopy; A03, Microfiche

Radar has been around for more than half a century now. During this time it has reached both widespread application and a high degree of sophistication. Still, it is far from being a mature science. Major improvements in concept, componentry and information exaction continue to make radar more capable in detecting and identifying targets. Parallel with this development, the concealment of military

targets is an ever-increasing necessity and is progressing with similar strides. A review of recent developments in the analysis of radar signatures of military targets is therefore timely and appropriate. The symposium addressed many aspects of this multi-faceted topic. Numerical target modeling holds great attraction. Methods are presented to render the problem computationally more efficient. Simulation and scaled measurements in comparison with full-size target measurements serve to build confidence in using a cost-effective combination of these techniques to determine radar cross section data. Environmental factors such as rain depolarization and surface multi-path propagation were considered, along with man-made chaff as they impact on radar. An important subject for study was the robustness of non-cooperative target identification based on target doppler characteristics, polarimetry and one- or two-dimensional imaging. The availability of large amounts of data from modern radar systems makes the automation of target detection almost mandatory. The benefits of different approaches are compared. Signature modification is a prerequisite for target survival in the sophisticated electronic warfare arena of the future. Papers ranged from low radar cross section structural designs and retrofits to active cancellation techniques.

Applications of a finite difference time domain method for the solution of the Maxwell's equations involving arbitrary shapes are presented. The method used is based on explicit Lax-Wendroff scheme applied to the transformed equations expressed in generalized coordinates. Only the scattered field variables are solved to evaluate the surface current and the bistatic radar cross section. The computer code developed is first calibrated with the analytical solutions and then the code is used to calculate the RCS for perfectly conducting arbitrary shapes immersed in transverse magnetic plane waves.

Computational electromagnetics and computational fluid dynamics have evolved as independent areas of numerical analysis, but the equations which are solved in these two areas are fundamentally similar. It therefore seems plausible that methods developed in one area should also be applicable to the other, with possible savings of time and computer resources. This paper describes a test of this idea: a general method originally developed for aerodynamics calculations by specialists at the Farnborough site of the Defence Research Agency (DRA) is now being adapted for electromagnetic calculations, with the collaboration of specialists at the DRA's Malvern site. The preliminary results are very encouraging.

This article describes a theoretical method for calculating the equivalent radar surface of a target illuminated by a plane or spherical electromagnetic wave. The method is based on the integral formula of Stratton Chu, simplified by the hypotheses of physical optics. Developed and set up in the form of the sermail calculations code by the Celar (Weapons Electronic Center), it is used particularly to check the quality of acquisitions at the great Solange Equivalent Radar Surface measurement base whose characteristics are reviewed. A comparison of the theoretical and experimental results obtained from some canonical target is also provided.

LOW FREQUENCY SCATTERING BY TARGETS ABOVE A GROUND PLANE

Dassios, George, Patras Univ., Greece; Kleinman, Ralph, Delaware Univ., USA; Apr. 1997; 10p; In English; See also 19970026663; Contract(s)/Grant(s): F49620-96-1-0039; AGARD-G-84; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Low frequency scattering by isolated targets in space has been well studied and there exists a general theory as well as explicit results in special target shapes. In the present paper we develop a comparable theory for low frequency scattering of targets above a flat plane. The presence of the ground plane has a considerable radar cross section of the scatterer and this effect is highly dependent on the boundary condition used to model the ground.

Parabolic equation (PE) techniques have been used for some time to solve various types of wave propagation problems. They provide an efficient solution for long-range forward propagation radar and sonar predictions. More recently, they have been applied to scattering problems, and in particular to RCS calculations. Our aim in this paper is to summarize the PE techniques currently available for RCS work and to give a few typical examples in two and three dimensions.

The fast multipole method (FMM) is used for the fast radar cross section (RCS) computation of large canonical two-dimensional geometries in both homogeneous and layered media. Numerical solution of electromagnetic scattering problems are invaluable in many real-life applications. However, real-life problems translated into very large

numerical problems and when accurate solutions are desired, the size of the problem that can be solved using traditional techniques is limited by the given computational resources.

STATISTICAL ANALYSIS OF PROPAGATION PARAMETERS FOR POLARIMETRIC RADAR MEASUREMENTS

Antar, Y. M. M., Royal Military Coll. of Canada, Canada; SantalladelRio, V., Universidad de Vigo, Spain; Apr. 1997; 10p; In English; See also 19970026663; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Analysis of the polarimetric scattering matrix or the covariance matrix has become an important tool in remote sensing applications. Propagation to and back from the target is affected by the medium. Rain media usually present some anisotropy that causes depolarization of the wave and can greatly affect either the scattering matrix or the covariance matrix obtained. Depolarization effects through propagation should then be corrected for. These effects can be determined and accounted for if the characteristic polarizations of the medium (those that propagate without changing their polarizations) and their respective propagation constants are known. In examining the back-scattering properties of rain media it is found that they present reflection symmetry. This is an important property that leads to linear and orthogonal characteristic polarizations. Measurement of the covariance matrix in the polarization base defined by the characteristic polarizations allows extraction of propagation parameters from the copolar power and copolar correlation terms. Different algorithms can be designed for its extraction. In order to be able to compare them, statistical analysis of polarization covariance matrix is performed. This analysis considers also the correlation effects between successive data samples.

The paper describes an approach to the simulation of radar signatures from large complex targets. The issue addressed is that given a subject radar target in the form of a geometrical design, is it possible to recognize redundancy in the electromagnetic radiation source which this target represents when illuminated by radar? This is a key issue since the task of directly evaluating the signature is often so compute intensive as to prohibit its use in a simulator.

After a review of the general problem inherent in the identification of non-cooperative radar targets and a brief look at the most promising identification techniques, this report describes the measurement bench that was designed and developed in the laboratories of the Royal Military Academy to measure the pulse response of three-dimensional targets. The originality of this bench essentially resides on the fact that measurement is done directly in the real-time frame and that there is no need for any anechoic chamber, as in the conventional frequency method to which it is compared. Checked out by means of canonical targets, the bench is now used for the experimental determination of the pulse response of any three-dimensional targets.

A novel broadband absorber is introduced. Instead of the classical voluminous carbon loaded foam, the new absorbing element is a thin metal layer of only some 10 nm thickness. Measurements of the electromagnetic specifications of anechoic chambers built with absorbers made of the new material have revealed a better field homogeneity than known from those built with the classical foam absorbers. Other properties are the light weight of the absorbers and they can be made from non-combustible material. The absorbing and low reflecting properties of the mesoscopic metal layers are effective up to infrared frequencies. There will be introduced some applications of the novel technology.

The material parameters, permittivity epsilon and permeability Mu, which are needed for the calculation of the mono- and bistatic radar cross section of complex structures, have been determined for a lot of samples in the frequency range from 8 GHz to 110 GHz. Three different methods, the measurement of the S-parameters in a waveguide, the measurement of the reflection or transmission factor under free space conditions, measurements of the reflection factor by a coaxial probe, have been applied and are described in detail. The quality of the results is dependent on the method chosen, as well as on the accuracy in the fabrication of the samples, which is in general more critical at higher frequencies. Some measurement results are presented and discussed in detail.

We developed instrumentation radars in the sub-mm and mm wavelength range for two dimensional (2-D) imaging. Salient features

of these systems are mechanical frequency shifting for a very high degree of phase stabilization and target precessional motion for cross-range/ cross-range imaging. We designed a cm wavelength radar which additionally uses a wideband waveform for ranging to permit three dimensional (3-D) imaging. The latter system is fully polarimetric. All radars use a form of moving target indicator (MTI) cancellation to suppress background clutter. The operation of these systems and examples of data measured on canonical bodies and model targets are discussed.

We consider the problem of imaging strongly scattering, penetrable targets by inverting scattered field data. We describe a method to recover images of strongly scattering targets based on a modification of the well-known technique of diffraction tomography. It is a nonlinear (differential cepstral) filtering process. In order to overcome the problems associated with limited angular measurements of the scattered field, as described by Lammers and Marr in the preceding paper, we have to incorporate Fourier-based methods for spectral estimation. The advantages and difficulties associated with this new method are described.

The radar, as a matter of fact, makes it possible to detect moving targets. The operators of the 2nd Light Cavalry can use their equipment to spot and locate miscellaneous vehicles (tanks, armored troop carriers, wheeled vehicles, etc.) but also much smaller targets, such as just one man.

MODELING OF ISAR IMAGERY FOR SHIPS

Emir, K., Netas Northern Electric Communications, Inc., Turkey; Topuz, E., Technical Univ. of Istanbul, Turkey; Apr. 1997; 6p; In English; See also 19970026663; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

An alternative approach is proposed for the modeling of ISAR imagery for ships, which can effectively be used to generate images in sufficient accuracy as to correctly represent the dominant scattering phenomena. This approach relies on doing some preprocessing on the data for each particular problem, so as to simplify the modeling of the ships surface. Our preliminary numerical results demonstrate that the proposed technique is computationally very efficient. Moreover, the generated data is sufficiently accurate and can be fed into the recently developed automatic classification algorithms which are based on localization of dominant scattering centers on the target.

This paper describes the construction and calibration of a signal generator for representing the distributed phasor vector radar signature of a chaff round. The fundamental approach together with some alternative methods of calibration are discussed, and some results are presented. The paper is written assuming that the reader is familiar with chaff, its terminology and its methods of deployment. The body of the paper concentrates on producing a model of chaff that is sufficiently accurate and adaptable to represent a given chaff round at a physical level. In particular, the possibility of using physical level Computer Aided Engineering (CAE) to calibrate the model is addressed.

ANALYSIS OF EXPERIMENTAL DATA FOR NCTR TARGET MODELLING

Moruzzis, Michel, Thomson-CSF, France; Guillerot, Jean-Claude, Thomson-CSF, France; Lestrade, Christian, Thomson-CSF, France; Apr. 1997; 8p; In English; See also 19970026663; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

In this paper one presents some experimental results obtained for different radar bands and different NCTR techniques. These results are then analysed in terms of robustness and one draws some trends regarding the kind of features which can be used for NCTR. Finally one suggests a method for designing NCTR systems based on both target and measurement conditions modeling.

The control of the radar signature for surface vessels is a key factor to their survivability. After a short reminder about the motivations for the knowledge and control of this signature, three main analysis methods are presented along with their advantages and drawbacks. Next, the HRB (High Resolution Bench) is described in detail as a large bandwidth polarimetric measurement equipment, developed by THOMSON-CSF Applications Radar, operated by the French Navy technical services, and which enables a refined analysis of the vessels signature, even in an environment comprising self-screening electromagnetic decoys. After a description of the measurement instrument and its operating modes, the characteristics of the measurements which the HRB can provide are presented as well as the refined analysis software for these signatures. Next the technical characteristics for the main components of the radar are detailed. Finally, the calibration problem posed by this type of large bandwidth polarimetric measurement equipment is briefly discussed.

EXPERIMENTAL ANALYSIS OF EFFECTS OF ANOMALIES IN STRUCTURE OF RADOMES ON RADOME'S PERFORMANCE

Celikel, Sadik, Second Air Supply and Maintenance Center Command, Turkey; Gorur, Adnan, Nigde Univ., Turkey; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

In this study, radome structures, located in the nose section of aircrafts, which protect radar antennas from adverse environmental effects, fit to aircraft structures aerodynamically but which differ from other parts of aircrafts in terms of electrical features have been examined basically. Effects of radome structural anomalies to radome electrical performance have been investigated by bonding mica plates

at some parts of electromagnetic window section of an F-4 nose radome which differ the thickness of the structure. Transmission loss, boresight error, boresight error measurements, have been achieved via B-350A Test Utility System. Consequently, experimental analysis of anomalies which occur as variation at density and thickness of radome structures have been evaluated.

MULTIFUNCTIONAL RADIO SYSTEMS FOR MULTINATIONAL FORCES

Mey, G., Ministry of Defence, Germany; Reitberger, P. H., Rohde and Schwartz, Germany; Jul. 1997; 8p; In English; See also 19970029347; Copyright Waived; Avail: CASI; A02, Hardcopy; A03, Microfiche

Modern technological and technical possibilities of multifunctional, fault-tolerant radio systems for armed forces operations are described. With the availability of new technologies it appears technically feasible to adjust the nationally diverse radio signal formats in multinational operations and to exchange them internationally without compromising any security interests of the operating forces. The central technical parameters of the participating nations' radio functions need to be exchanged for this purpose. However, such parameter exchange does not restrict the use of nationally defined waveforms. Due to present capabilities, the simultaneous use of radio functions on a national and multinational basis is possible for cooperating forces and, due to the expected benefits, ought to be recommended. Command distribution via both national communication channels and multinational fast communication channels permits nationally supported multinational command structures. A unique way to achieve different national COMSEC codes will be derived from so-called c*) Codes. The c code can be transmitted via national and multinational protected channels without any loss of security. Armed forces require a new, additional possibility of operating with multifunctional radio systems in missions with high security requirements for the communication equipments. During mission preparation, the ECCM measures for the communication systems are designed especially for the mission. Such radio waveforms tailored for a specific mission will result in greater protection compared with generally defined radio waveforms, which are partially known worldwide, without losing the possibility of cooperating with other participating forces, by using exchangeable waveforms for these communication links.

AIRBORNE AND SPACEBORNE SAR SYSTEMS: POSSIBILITIES AND LIMITATIONS FOR MILITARY USE

Keydel, Wolfgang, Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 10p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

Synthetic Aperture Radar (SAR) is perfectly suited for aerospace surveillance and reconnaissance systems. In principal, SAR combines the advantages of microwave systems like weather independence, optical visibility, penetration capability. The state of the art as well as the development of technique and technologies needed and possibilities of future systems will be shown briefly.

ULTRA-WIDE-BAND TECHNIQUES AND THEIR PRACTICAL USES TECHNIQUES A BANDE ULTRA-LARGE ET APPLICATIONS

Piette, Marc, Royal Military Academy, Belgium; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 14p; Summary translated by Schreiber; In French; See also 19980016571; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The purpose of this communication is to present an introduction to ultra-wide-band radars and their technology. After defining the terminology inherent in these new radars and describing it specifically, we describe the form of the signals they emit by comparing them -- in terms of time and frequency -- to the signals that are emitted by the conventional radars. We then move on to a review of the various types of transmitters that can be used, the specific antennas that were developed recently, and the possible structures of the receiver. Finally, we briefly present the techniques of analysis and processing of signals that are specifically related to nonsinusoidal and pulse signals, before stating some conclusions as to future prospects.

HIGH-POWER MICROWAVES EFFECTS ON SMART ELECTRONIC WEAPON SYSTEMS

Nitsch, J., Otto-von-Guericke Univ., Germany; Bohl, J., Diehl G.m.b.H. und Co., Germany; Straehle, U., Ministry of Defence, Germany; Kaiser, A., German Armed Forces Scientific Inst. for Protection Technologies, Germany; Meyer, L., German Armed Forces Scientific Inst. for Protection Technologies, Germany; Vogel, H. J., German Armed Forces Scientific Inst. for Protection Technologies, Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 14p; In English; See also 19980016571; Original contains color illustrations; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

In this paper we describe the coupling of microwaves to smart electronic weapon systems. Analytical and numerical calculations of an almost real model of a weapon system give a first idea concerning the results of a strong interaction of an electromagnetic wave with the system under consideration. Subsequent experiments with the passive system confirm the expected results and/or add new, sometimes unexpected ones to the former. They together form the basis for the final tests with the active smart system. Whereas the passive tests mainly are performed with low power excitation in the cw-modus, experiments with the active system are conducted with quite different power levels and the variation of many other HPM-parameters. The magnitudes of the perturbation quantities inside the system are measured and stored and serve as input data for a flightpath simulation program. With the aid of such a program one can make a prediction whether or not the smart weapon system can fulfill its mission. It is shown that interferences lasting longer than about 1.5 s lead to mission interruption. Hardening and defense aspects are discussed at the end of the paper.

TRENDS IN AIRBORNE ELECTRONIC WARFARE: A EUROPEAN PERSPECTIVE

Baratault, P., Thomson-CSF, France; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 8p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

Electronic warfare is one of the areas in which each major nation has tried to stay largely independent. As the European construction programme continues and budgets shrink, it would be reasonable to assume that this situation is now going to change quite quickly. In any case, the industry must be prepared for this scenario, even if the decisions are basically political. The first point examined in this paper is that electronic warfare should be considered as a whole. It should no longer be approached on a programme-by-programme basis, or just in terms of equipment. On the contrary, our vision of electronic warfare should encompass intelligence gathering (to define the threats), technico-operational simulation (to specify which systems and equipment are needed to deal with the threats), evaluation, tests, and life cycle support. and our approach to electronic warfare should also include all the spectral components of known or predictable threats. A second consideration is that electronic warfare can no longer be dealt with as a separate area of interest. This is partly because of cost constraints, but partly because of the specific technical problems involved in co-siting different systems on board on an aircraft. It is becoming more

and more vital to make different systems share technical functions, apertures and time slots. Current developments in modular integrated avionics are moving in this direction. Further efforts are needed in the field of sensors and antennas. The third consideration discussed here is primarily of concern to our industry, but it cannot leave governments indifferent, as what is at stake is Europe's independence. I am talking here of the vital importance of maintaining European capacity in key technologies for which commercial applications cannot yet generate sufficient volume or which have cycle times that are incompatible with military programmes.

FUTURE TRENDS IN IMAGE PROCESSING AND PATTERN RECOGNITION

Acheroy, Marc, Royal Military Academy, Belgium; Korn, Axel, Fraunhofer-Inst. fuer Informations- und Datenverarbeitung, Germany; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 10p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The strong evolution of the scientific background and of the imaging technology is transforming image processing in a discipline where the boundaries between the sensor system, the processing system and the visualization and/or decision making system are vanishing. Indeed, it is more and more difficult to split the design of signal processing algorithms from the design of pattern recognition algorithms or the preprocessing dedicated to the sensor system from the decision making process. Sensor systems are also evolving very fast, their variety increases and their resolution is getting better in all domains (temporal, spatial and wavelength domains). Therefore, they are one of the fundamental reasons for the modern evolution in processing algorithms and hardware design, especially in data fusion and parallel processing. The design of modern pattern recognition systems, that show an intelligent behaviour, has to cope with the huge multiplicity of inputs at different levels. These inputs must be combined and fused in order to extract the useful information and to make possible the decision making. Finally, the computer hardware performance and integration fortunately still increase exponentially so that it still remains possible to implement the more and more sophisticated, real-time or near real-time applications on existing hardware.

REAL TIME SPECIFICATION OF THE BATTLE SPACE ENVIRONMENT AND ITS EFFECTS ON RF MILITARY SYSTEMS

Cannon, Paul S., Defence Evaluation Research Agency, UK; Richter, Juergen H., Naval Air Warfare Center, USA; Kossey, Paul A., Phillips Lab., USA; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 12p; In English; See also 19980016571; Original contains color illustrations; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The critical nature of electromagnetic propagation assessment in the development of a wide range of sensor, communications, and weapon systems is highlighted. A brief description of the Battle Space Environment, together with methods to specify it are given. A number of contemporary decision aids are used to illustrate both the importance of accurate, timely environmental specification, and of accurate ray-tracing, to NATO operations. The importance of using new sensors, data fusion and advanced computer assets is identified.

FROM INFORMATION WARFARE TO INFORMATION POWER: A NEW PARADIGM FOR NATIONAL SECURITY IN THE INFORMATION AGE

Kuehl, Dan, National Defense Univ., USA; Future Aerospace

Technology in the Service of the Alliance; Dec. 1997; Volume 2; 10p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A02, Hardcopy; A02, Microfiche

The passage of the Goldwater-Nichols Act in 1986 generated a new emphasis on "jointness" in the American military. Current concepts of jointness and joint operations are encapsulated in the existing definition found in Joint Publication 1-02, which defines joint as "activities, operations, organizations, etc., in which elements of more than one Service of the same nation participate." The question at hand, however, is whether this concept, centered on blending the operations and capabilities of the four military Services, is sufficient for information warfare (IW) and the needs of national security in the information age. Are the impacts and implications of the information revolution so widespread that they necessitate a new perspective on who should be covered by the umbrella of jointness? The thesis of this paper is that the current Service-focused understanding of jointness is insufficient because it is too narrow, and that a broader and more inclusive concept that incorporates all of the various elements of national information power is necessary.

MODELLING AND SIMULATION OF COMMUNICATION SYSTEMS

Alston, I. D., GEC-Marconi Research Centre, UK; Currie, J. C., GEC-Marconi Research Centre, UK; Dearlove, C. M., GEC-Marconi Research Centre, UK; Future Aerospace Technology in the Service of the Alliance; Dec. 1997; Volume 2; 12p; In English; See also 19980016571; Copyright Waived; Avail: CASI; A03, Hardcopy; A02, Microfiche

The design of digital communication systems involves the definition of the system architecture (e.g. network topology, protocols); the design and modelling of the algorithms/behaviour of the system (e.g. signal processing functions); the design of the hardware/software architecture to be employed; and finally, implementation of the algorithms on the chosen architecture. During this design lifecycle the performance of the communications system can be evaluated in three ways, the paper will briefly discuss the characteristics of these methods and highlight when computer modelling/simulation is the best and most efficient way forward in order to gain an understanding of a communication system and an estimate of its performance. The paper will discuss the migration from computer modelling using standard high-level languages such as FORTRAN towards the use of high level design and simulation packages. The paper will show how such a commercially available package was used to model the physical layer of a public air-to-ground telephone system. The paper will also show how the modelling activity was used within the standardization process and how these new tools allow models to evolve easily introducing more and more detail until it represents a very accurate model of the real system. The paper will also show how subsequently the computer model was used to assist in the implementation and testing phase of the project. Finally the paper will discuss the concept of rapid prototyping and its advantages and show how such a modelling tool can also be used to produce prototype equipment.

(NU) The FGAN-FHP MEMPHIS radar transmits simultaneously at 35 GHz and 94 GHz. Accordingly, when flown in a side-looking configuration, closely related SAR images can be generated for both frequencies. These two images can be combined for the purpose of target detection and discrimination. (NU) It is analyzed how this combination can be performed, and how one gains with respect to speckle reduction, target-to-background contrast, detection probability and false alarm rate. For this purpose, a subsequent feature

based prescreener and a subsequent feature based discrimination stage. (NU) For multi-look images that are mapped to the ground it is found that the combination of two different frequencies with like polarization provides better speckle reduction and target-to-background enhancement than the combination of two orthogonal polarization channels at the same frequency. The detection/discrimination results depend on how precisely the two images are registered.

The variety of recent conflicts in which allied forces participated has demonstrated the limitations of air-to-ground existing armament systems (strong constraints on use, armaments that are too specific, insufficient firing ranges with respect to ground-to-air defences, etc.). France, for this reason, has set the goal of developing a new kind of tactical armament, which would be complementary to SCALP type cruise missiles. This modular design weapon system, designated AASM (modular air-to-ground weapon), will have ranges greater than 15 km and should be capable of two categories of metric and decametric precision. Before firing the weapons, it is necessary to carry out certain number of operations such as detection, recognition and location determination of the targets to be processed.

METHOD OF EVALUATING PERFORMANCE LEVEL OF A MULTIPLE-SENSOR TRACKING DEVICE METHODE D'EVALUATION DES PERFORMANCES D'UNE POURSUITE MULTICAPTEUR

Desbois, M., North Atlantic Treaty Organization, Netherlands; Apr. 1998; 9p; In French; See also 19980210650; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The purpose of this presentation is to describe the methodology which has been developed for evaluation of multiple-sensor tracking within the C3 agency of NATO. This methodology originally was developed for the purpose of quantifying the performance requirements in terms that are applicable to establishment of the recognized air picture (RAP) within the framework of drafting specifications for the future command and control system of air operations (air command and control system, ACCS) of NATO. A certain number of performance measurements (MOPs) have thereby been defined. A process of segmentation of the paths and trajectories of the followed targets is necessary as a prior condition to calculating one part of these measurements: description of this segmentation is also included in the developed methodology, just as the involvement of different filters which allow a targeted study of monitoring performance.

ARTAS: MULTISENSOR TRACKING IN AN ATC ENVIRONMENT
Hogendoorn, R. A., National Aerospace Lab., Netherlands; Neven, W. H. L., National Aerospace Lab., Netherlands; Apr. 1998; 8p; In English; See also 19980210650; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

ARTAS (an acronym for ATC Radar Tracker and Server) is currently in pre-operational test at four different sites in France, Germany and the Netherlands. The ARTAS system consists of a tracker, responsible for maintaining up-to-date target state vectors, and a server, which handles client subscriptions (e.g. from the ATC display system) and delivers the target state vectors to these clients. An ARTAS system co-operates with adjacent ARTAS systems by exchanging target state vector information. The main features of the ARTAS Tracker are; tracking with up to thirty radars (PR, SSR or

CMB); on-line estimation of the radar systematic errors; online estimation of the radar accuracy and coverage; high-accuracy position and velocity-vector estimation; responsiveness to target maneuvers; insensitivity to clutter; and target classification. The tracking filters are interacting multiple-model (IMM)-based filters, a four-model filter for high speed and highly maneuvering target and a two-model filter for low-speed targets. The plot-to-track association is based on probabilistic data association (PDA), with special joint probabilistic data association (JPDA) algorithms in case of target close approach situations. Track initiation is done by time-reversed multiple-hypothesis tracking. Target classification is based on Shafer-Dempster reasoning.

LOW ALTITUDE WAVE PROPAGATION EFFECTS IN A TRANSMITTER INDEPENDENT RECEIVER NETWORK

Farsaris, Nikos J., Technical Univ. of Crete, Greece; Stavroulakis, Peter P., Technical Univ. of Crete, Greece; Apr. 1998; 5p; In English; See also 19980210650; Copyright Waived; Avail: CASI; A01, Hardcopy; A04, Microfiche

For the design and implementation of a Passive Multistatic Early Warning and/or Fire Control Radar (T.I.R.N., Transmitter Independent Receiver Network) many aspects include the environmental conditions that T.I.R.N.'s may encounter at operational conditions. Even operating in a standard troposphere, the result of the refraction phenomenon is the curved propagation of the electromagnetic waves. The problem becomes more complicated at low altitudes, where tropospheric refractive index variability, multipath propagation and clutter (sea or ground) must be taken into consideration in order to avoid erroneous results for the location of a target as well as its velocity estimation. Although simplified models of the above environmental parameters are used in this analysis, (e.g. lateral refraction variability is not studied here, and Weibull Distributions Model is taken for granted as regards the sea clutter), useful results can be produced for the evaluation of multistatic systems. In this paper a four-receiver model using the signal of a non-cooperative transmitter is evaluated for its sensitivity at the above conditions and is compared with a conventional monostatic radar operating with the same signal. It is shown that the T.I.R.N. proposed is a more efficient system than its monostatic equivalent. The results presented, despite of being strictly theoretical (not yet evaluated in real operational conditions) may help the design of multistatic radars.

High frequency reliable radio communications in decametric band is currently based on procedure such as ALE (Automatic Link Establishment), RTCE (Real Time Channel Evaluation) ... which purpose is to test channel transmission capacity and interferences level. Establishment tests, made in real time, give interesting results by using long time experienced procedures with very good instantaneous reliabilities. Though, procedure can be improved with short time prevision of transmission channel characteristics and with interferences forecasting which are numerous in decametric band. Ionospheric forecasting methods allow to take into account ionospheric transmission characteristic. It is supposed that a very short time forecasting method (1 to 2 hours) or that a short time method (24 to 48 hours) is implemented. Interference forecasting is of prime importance in prevision of good establishment of links. Electromagnetic spectrum observation in HF band shows that: a Correlation from a day to another of interferences levels are often strong; Spectral correlations are good until distance of about 400/500 km; Interferences levels are depen-

dent of observation azimuth; and Spectral occupancy is correlated with critical frequency FoF2. Taking into account these characteristics lead to consider the establishment of interferences level forecasting and the critical frequency of F2 layer. Jamming level characterization is introduced by considering the notion of clear frequency for a specified level. Frequency is supposed to be clear for a threshold S if the interferences level remains lower to this threshold. Clearness probability can be determined for each traffic band and we can plot surface of probability that a clear frequency one day remains clear the following days. These surfaces plotted as a function of the threshold and the forecast horizon are shown. Correlation between spectral occupancy and FoF2 frequency is also modelised. Comparison between FoF2 frequency determined by zenithal sounding with measurement of occupancy - MIF - has been proved very satisfying. A data fusion processing lead to a totally passive method of real time network management.

COLLATION OF DATA AND EXTREMELY LOW-POWER FINDER FOR TELECOMMUNICATIONS FUSION DE DONNEES ET SONDEUR A EXTREMEMENT FAIBLE PUISSANCE POUR TELECOMMUNICATIONS

Goutelard, C., Laboratoire d'Etude des Transmissions Ionosphériques, France; Pautot, C., Laboratoire d'Etude des Transmissions Ionosphériques, France; Apr. 1998; 6p; In French; See also 19980210650; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Radio communications in decametric band are made difficult by important variability of transmission channel and by level and density of interferences which congest this part of the radioelectric spectrum. Link establishment methods are currently based on a preliminary sounding of the channels and a scrutiny of interference spectrum. This method is implemented by systems which works alternately with radio communication systems or use independent test system. The disadvantages of these methods lie in an uneasy uses and a often insufficient periodic actualisation of estimation. Implementation of system allowing to test channel with extremely low emitted power gives a new way very interesting to establish links and to keep them. Electromagnetic soundings of the ionosphere is limited by the problem of electromagnetic pollution they create, which limits their use, and by the high sensitivity of the interference included in the band. The emitted power reduction solves the first point, on condition that sensitivity to the jammers remains acceptable. This results is obtained for implementation of non linear signal processing which allows to choose the wave shape and coding by solving an optimisation problem without constraints. Results obtained allows to do soundings with very low power. We can notice the protection given by the new method. These new capacities allow a permanent ionospheric sounding, on all the frequencies. A data fusion can then be made taking into account available informations, especially ionospheric disturbances. This method can be applied in particular to the network management to improve their efficiency.

A new method of SSL (Single Site Location) is presented which makes use of multi-sensor information. Also, unlike conventional SSL methods which generally ray-trace backwards using a single angle of incidence and azimuth, this method uses the incident angles of two or more simultaneous paths (e.g. 1 and 2 hop F2) to determine both an updated ionosphere model at the reflection point(s) and the location of the target transmitter. The angles of azimuth of arrival and elevation are determined using a super-resolution algorithm to decompose the multipath wavefield received on an antenna array. Analytic models are

used to approximate the ionosphere and determine propagation paths. If vertical ionospheric sounder data is available, the obtained electron density profile can be fitted using quasi-parabolic segments (MQP model) and parameters of this model optimised in the minimisation procedure. A Nelder Mead simplex algorithm is used for the function minimisation. Greater accuracy in unknown transmitter location can be achieved by including additional constraints in the system such as measured elevation angles of known transmitters. The SSL determination is performed under MATLAB via a menu-driven graphical user interface. This employs pulldown menus for data input, program choice, ionospheric profile plotting and presentation of results.

SMART ANTENNA ARRAY PROCESSING FOR SPREAD SPECTRUM WIRELESS COMMUNICATION SYSTEMS

Huang, Y. F., Notre Dame Univ., USA; Kapoor, S., Notre Dame Univ., USA; Gollamudi, S., Notre Dame Univ., USA; Nagaraj, S., Notre Dame Univ., USA; Apr. 1998; 10p; In English; See also 19980210650; Contract(s)/Grant(s): NSF MIP-97-05173; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

This paper examines the problem of incorporating smart antennas in wireless DS-CDMA systems. The use of array signal processing in DS-CDMA systems offers the possibility of jointly utilizing code and spatial resources to achieve superior performance compared to conventional multiple-access methods. The development of interference suppression techniques is essential to take full advantage of the available radio resources and requires data fusion in the spatial and code domains. Spatial signal processing can also lead to faster and robust synchronization and provide the capability to rapidly adapt to channel fading, co-channel and adjacent channel interferers. The overall method is suitable for real-time implementation and can lead to a direct increase in the overall capacity, quality and coverage of these systems.

PROPAGATION DIVERSITY CONSTRAINTS ON RECEPTION OF GPS SIGNALS AT HIGH AND EQUATORIAL LATITUDES

Aarons, Jules, Boston Univ., USA; Lin, Bosheng, Boston Univ., USA; Apr. 1998; 10p; In English; See also 19980210650; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

The coming of years of high solar flux, starting in 1999, will bring propagation problems to some users of GPS; we are concerned with ionospheric irregularities which produce phase and amplitude scintillation. The knowledge of when deteriorated signals will occur and their characteristics can help minimize their impact or at least allow users to understand that the fading phenomena are of natural origin rather than equipment related. At equatorial anomaly latitudes, fades of 20 dB at GPS frequencies have been observed in years of high solar flux; according to receiver experts these are enough to disturb any equipment. The sophistication of the equipment in moving through these signal problems is a function of hardware and complexity of software. Knowledge of diversity can help to minimize the effect of temporary loss of signal. The equatorial region irregularity structures are dominated by patches of irregularities which are frequently of the order of 100-200 km in their East West extent. At times these extensions may be exceeded. In addition their effective magnetic North South dimensions may be effective to a few thousand kilometers along the earth's magnetic field. If the altitude that the plume of irregularities reached at the magnetic equator is high, the effects reach the anomaly region with its high electron density and show strong scintillation intensities. New data on the variety of altitudes of irregularities at the equator puts limits on forecasting of some structures but hope for forecasting some major plumes. In the polar region severe problems are not expected to surface until 1999 since polar irregularities have been found to be a function of solar flux. In this area diversity of propagation paths can play an important role. The irregularity region at auroral latitudes is primarily affected by individual magnetic storms which can occur during any phase of the sunspot cycle. Irregularity intensity is a

function of various parameters of the magnetic storm relative to that station. Illustrations of GPS phase fluctuations will be shown as individual storms develop. New data clearly show the forecasting possibilities when using timing of the auroral oval occurrence at a site as a means of prediction. L Band is to be used in the downlink of new systems proposed and being initiated for personal communications. Low link margins are forecast for several systems to be in the range 6 to 10 dB. These levels indicate that fading due to the ionospheric irregularities such as discussed in these GPS studies will cause problems.

METEOROLOGICAL DATA FUSION TO ASSESS EM/EO PROPAGATION CONDITIONS IN COASTAL ENVIRONMENTS

Rosenthal, J., Naval Air Warfare Center, USA; Helvey, R., Naval Air Warfare Center, USA; Greiman, P., Naval Air Warfare Center, USA; McGovern, M., Naval Air Warfare Center, USA; Apr. 1998; 7p; In English; See also 19980210650; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

EM/EO propagation conditions can be estimated along specific routes or regions of interest by fusing on one display, the visible satellite imagery showing cloud cover, the operational geometry, and derived quantities such as duct height estimated from the IR duct technique. In addition, by compositing conditions over a set of similar synoptic events, and when also fused with averaged synoptic field gridded data, an average depiction of duct height and associated variability can be obtained. To the extent the cases selected are typical of that type of event, the averaged picture can be used to forecast or estimate the distribution of EM/EO parameters in the near future if confidence exists in the forecast synoptic situation. Additional compositing is underway to broaden the range of synoptic weather types and regions examined.

COMMUNICATIONS MANAGEMENT IN BATTLESPACE DATA FUSION

Deaves, R. H., British Aerospace Public Ltd. Co., UK; Nicholson, D., British Aerospace Public Ltd. Co., UK; Greenway, P., British Aerospace Public Ltd. Co., UK; Vangasse, P., British Aerospace Public Ltd. Co., UK; Apr. 1998; 9p; In English; See also 19980210650; Copyright Waived; Avail: CASI; A02, Hardcopy; A04, Microfiche

Algorithms for managing bandwidth-limited communications links in a multiplatform and multi-target battlespace data fusion scenario are investigated. The platform architecture is modelled on a fully connected decentralised system based on a simplified tactical air warfare scenario. Information on filters on each platform maintain track estimates for each target. These are transmitted around the system in accord with a time-division- multiple-access communications protocol based on JTIDS. Here we address a practical limitations on the communications bandwidth: it unable to support the full set of state information for all of the targets each communications cycle. Strategies must therefore be found to manage the bandwidth. In this paper we consider two different communications management algorithms: (i) a somewhat ad hoc cyclic, or round-robin, algorithm, and (ii) more principled information theoretic algorithm. In general we find that the system has better tracking performance under the information theoretic algorithm than it does for the round-robin algorithm. This result appears to be fairly robust to uncertainties in a transmitting platform's prediction of the state estimates that are currently being maintained at the recipient platforms. In practice since the information theoretic algorithm is more computationally costly to implement than the round-robin algorithm the decision of whether or not to employ intelligent communications management is likely to depend upon the severity of the

bandwidth constraint, the number and type of tracked targets, and the predictive power of a platform with regard to other platforms in the network.

INTEGRATED DATA LINK FOR UTA APPLICATIONS: DESIGN CONSIDERATIONS AND DEVELOPMENT RESULTS

Blanchi, L., Marconi S.p.A., Italy; Battaini, G., Marconi S.p.A., Italy; Scazzola, G. L., Marconi S.p.A., Italy; Crovari, E., Marconi S.p.A., Italy; Jul. 1998; 16p; In English; See also 19990007836; Copyright Waived; Avail: CASI; A03, Hardcopy; A03, Microfiche

The UTA (Unmanned Tactical Aircraft) or, in general, the UAV (Unmanned Air Vehicle) typical requirements for either non-lethal or lethal tactical missions, imply both the capability to transmit, by means of a Data Link, real-time data (for instance IR, Video, Radar or Navigation Data) and to receive commands (to reprogram partially or completely the mission profile) to/from Ground Stations. The paper faces various aspects related to Data Links for UTA/UAV, presents system considerations and describes the development results obtained with the J Band UAV Data Link realized in Marconi and provided to Italian MoD.

Under a contract awarded in 1994 by French MOD (DGA), THOMSON-CSF has developed a demonstrator for a SAR/MTI Air-Ground Surveillance radar on low speed UAVs. After having explained the operational requirement (part 2) and the method used to develop CRESUS (part 3), the principal choices made for CRESUS are explained (part 4), especially the choice of medium range. This range enables one to take advantage, at the maximum possible extent, of the intrinsic features of a radar, that is to say its capability to look through the clouds and, as a direct consequence, its ability to observe from a higher and farther position. A description of MTI and SAR signal processing (Part 5), performances and characteristics (part 6), a physical and functional description (part 7) and a description of the ground segment (part 8) are then given. The conclusion (part 9) emphasizes the versatility of the demonstrator since it can be improved, at low cost, by adding a high resolution SAR mode. Furthermore a low cost installation of the final radar on different classes of UAVs (tactical, MALE, ...) is possible.

PRECISION POINTING AND TRACKING FOR TARGETING/FIRE CONTROL

King, T., Advisory Group for Aerospace Research and Development, France; Aerospace 2020; Sep. 1997; Volume 3, 66-67; In English; See also 19990014353; Copyright Waived; Avail: CASI; A01, Hardcopy; A02, Microfiche

Precision Pointing and Tracking is required in a number of military aerospace electro-optic (E-O) application areas including: air-to-ground E-O targeting; air-to-air sensing and targeting; IR Countermeasures (IRCM) and E-O Countermeasures (EOCM). Performance improvements of at least an order of magnitude are required for weapon systems that will be in service within the 2020 timeframe. The ability to track the target is a function of the sightline dynamic performance and stability, the detector sensitivity and resolution, and the tracking algorithms. The technical requirements for these capabilities are discussed, including: high levels of absolute pointing accuracy, pointing bandwidth, short-term pointing stability and jitter. Among the

various types of solutions discussed, 'inertialess' beam-steering via electro-optic sightline deflectors provides one possible solution to the bandwidth problem. In addition, future improvements will be obtained via algorithms which incorporate 3-D terrain data closely linked to the E-O system.

The identification, targeting and kill of critical targets, particularly targets that are mobile, is of extreme importance to the success of missions. To accomplish this, capabilities such as real-time mission (re)planning, location and identification of targets and real-time weapon guidance are required. Technologies needed to accomplish this are real-time data base management, fusion of on/off board data, algorithms for the detection and identification of targets, significant processor and memory capabilities and means to allocate these resources in a flexible manner.

In response to know deficiencies and advances in technology, information systems within the Department of Defense are migrating to compliance with the Defence Information System Agency's (DISA) Defence Information Infrastructure Common Operating Environment to ensure interoperability. The Medical Health Services System (MHSS) has been working to condense its myriad of non-interoperable systems into a family of interoperable systems that meet the needs of all the same architecture protocols as the tactical operational systems. This interoperability will contribute to improved situational awareness, tactical integrity, and command and control while supporting the warfighter.

DESIGN CONSIDERATIONS FOR A SUBOPTIMAL KALMAN FILTER

Difilippo, D. J., Defence Research Establishment Ottawa, Canada; AGARD, Aerospace Navigation Systems; Jun 1, 1995, p 295-311; In English; See also 19960003395; Copyright; Avail: CASI; A03, Hardcopy; A04, Microfiche

In designing a suboptimal Kalman filter, the designer must decide how to simplify the system error model without causing the filter estimation errors to increase to unacceptable levels. Deletion of certain error states and decoupling of error state dynamics are the two principal model simplifications that are commonly used in suboptimal filter design. For the most part, the decisions as to which error states can be deleted or decoupled are based on the designer's understanding of the physics of the particular system. Consequently, the details of a suboptimal design are usually unique to the specific application. In this paper, the process of designing a suboptimal Kalman filter is illustrated for the case of an airborne transfer-of-align-

ment (TOA) system used for synthetic aperture radar (SAR) motion compensation. In this application, the filter must continuously transfer the alignment of an onboard Doppler-damped master inertial navigation system (INS) to a strapdown navigator that processes information from a less accurate inertial measurement unit (IMU) mounted on the radar antenna. The IMU is used to measure spurious antenna motion during the SAR imaging interval, so that compensating phase corrections can be computed and applied to the radar returns, thereby presenting image degradation that would otherwise result from such motions. The principles of SAR are described in many references, for instance. The primary function of the TOA Kalman filter in a SAR motion compensation system is to control strapdown navigator attitude errors, and to a less degree, velocity and heading errors. Unlike a classical navigation application, absolute positional accuracy is not important. The motion compensation requirements for SAR imaging are discussed in some detail. This TOA application is particularly appropriate as a vehicle for discussing suboptimal filter design, because the system contains features that can be exploited to allow both deletion and decoupling of error states. In Section 2, a high-level background description of a SAR motion compensation system that incorporates a TOA Kalman filter is given. The optimal TOA filter design is presented in Section 3 with some simulation results to indicate potential filter performance. In Section 4, the suboptimal Kalman filter configuration is derived. Simulation results are also shown in this section to allow comparison between suboptimal and optimal filter performances. Conclusions are contained in Section 5.

M., Organisatie voor Toegepast Natuurwetenschappelijk Onderzoek, Netherlands; Schouten, Jan M., Naval Electronics and Optics Establishment, Netherlands; AGARD, High Power Microwaves (HPM), Volume 1; Mar 1, 1995, 10 p; In English; Copyright; Avail: CASI; A02, Hardcopy; A03, Microfiche

Modern warfare requires high levels of microwave power for various applications. Semiconductors are only suitable for low and medium power levels, for high power generation microwave tubes are the most effective solution. The paper will give an overview of present and future trends in high power microwave systems, based on electron beam tubes.
